THE Institution of Mechanical Engineers, before which Prof A S Eddington recently delivered the Thomas Hawksley lecture on "Engineering Principles in the Machinery of the Stars," was founded in 1847 at Birmingham with George Stephenson as its president Thirty years later its increasing activities led to its removal to London, and its present fine headquarters in Storey's Gate has been the scene of many notable gatherings The president this year is Mr R W Allen, of the Queen's Engineering Works, Bedford, while the president elect is Mr Daniel Adamson of Manchester Its membership is more than 10,000 and its income about £30,000 per annum It has initiated and carried out much important research work, it has representatives on numerous conferences, boards, and institutions, it maintains various provincial and overseas branches, and in conjunction with the Board of Education it conducts

examinations for National Certificates and Diplomas in Mechanical Engineering at more than one hundred technical schools and colleges The Thomas Hawksley Lecture was founded by the late Charles Hawksley (1839–1917) to commemorate the centenary of the birth of his father, Thomas Hawksley (1807–1893), one of the most distinguished waterworks engineers of his time, who served as president of the Institution of Civil Engineers and of the Institution of Mechanical Engineers One of the greatest works with which he was associated was the Lake Vyrnwy Scheme, North Wales, for the water supply of Liverpool

One hundred years ago a young musician, Louis Braille, blinded at the age of three, overcame his difficulty by the invention of a system of six dots whereby it was possible to emboss music, literature, and numerals Braille was born at Coupvray, near Paris, in 1809, and died in 1852, having been a pupil and for twenty six years a professor in the Institution des Jeunes Aveugles at Paris In connexion with the centenary of the invention, the National Institute for the Blind, which has issued millions of copies of music, books, etc , is appealing for funds for its work The appeal is addressed primarily to musicians, and it is proposed to have a performance of Mendelssohn's famous "Hymn of Praise," written in 1840 in connexion with the erection of the monument to Gutenberg on the fourth centenary of the invention of printing It is in this work that the words "The night is departing" occur

The first public school for the blind was established in Paris in 1784, the first in England was that at Liverpool opened in 1791, and the first in London dates from 1799 That in Paris was founded by Valentine Haüy (1746–1822), the brother of the famous crystallographer René Haüy (1743–1822), and it was Valentine Haüy who began printing in embossed characters for the blind Many men of science have suffered from blindness Galileo and Euler became blind Nicholas Saunderson, for a long time Lucasian professor of mathematics at Cambridge, was blind from the age of one, and H M Taylor, at the time of his death in 1927 senior fellow of Trinity College, Cambridge, did most remarkable work by translating mathematical volumes into Braille after he became blind at fifty two years of age The Belgian physicist Plateau became blind at the age of forty two, but with the aid of his wife and son continued to carry on his work in physiological optics and molecular physics, and at the age of seventy-two published a valuable contribution to the knowledge of capillary attraction

A new scientific expedition to the Antarctic under the leadership of Sir Douglas Mawson is now being organised The *Times* announces that the British government has given the *Discovery*, and that the Australian government is providing the necessary funds The government of New Zealand is also contributing The expedition is designed to explore the region between the Ross Sea and Enderby Land and to continue the work carried out in that area by Sir Douglas Mawson and Capt J K Davis in the Australasian Antarctic Expedition of 1911–14 Capt Davis is again to go with Sir Douglas Mawson and will be in command of the *Discovery* Much of the coast line towards Enderby Land is still unknown, and Enderby Land itself has never been visited since its discovery in 1832 Aeroplanes will be useful for inland survey The study of meteorological conditions will enable the relationships between the climates of Antarctica and Australia to be determined more accurately Much attention will be paid to the distribution of whales, in view of the spread of commercial whaling to those waters The expedition will sail from Australia towards the end of this year The combination of aeroplane reconnaissance and detailed ground work should result in discoveries of the highest value

A paper was read before the Surveyors' Institution on Feb 4, by Mr H J Vaughan, on "The Significance of the Timber Merchant in Estate Forestry" Mr Vaughan, who is now managing a large estate, in addition to taking a keen interest in the planting and growing of trees, has had the somewhat unique experience of having spent two years in close association with a large firm of English timber merchants in the south of England He says, in his opening paragraph, that "it seems to me that some even of our eminent foresters tend to lose sight of the saw bench when advocating and putting into practice schemes of afforestation or re planting" After glancing at the sporting and amenity aspects of woodlands, Mr Vaughan pointed out that what the timber merchant wants is a regular and trustworthy source of supply of his raw material, and that the management of private woodlands in the past has not fulfilled this desire This is the cause to some degreee of the low prices offered to owners for their trees, and for the high freights charged by railways for the carriage of timber After contrasting some of our best hardwoods with the softwood conifers, Mr Vaughan said he doubted whether Great Britain would ever be able to compete with tho Scandinavian countries in this class of material In discussing the work of the Forestry Commissioners and their concentration on planting softwoods and purchase of land for this purpose, Mr Vaughan expressed the opinion that it would be better to concentrate on growing hardwoods wherever possible, some of our native trees of this class having a real superiority, rather than to try to meet a questionable world famine with what is bound to be a very small proportion of our total requirements of coniferous softwoods for building and for constructional work Mr Vaughan considers it a wrong policy to plant conifers on areas where valuable hardwoods would grow

The Department of Entomology of the British Museum (Natural History) has recently received through Mr P A Buxton, of the London School of Hygiene and Tropical Medicine, specimens of a new genus and species of parasitic Hymenoptera (Ichneumonidæ), bred from the grubs of *Cladocera nigro-ornata*, a beetle used by the Bushmen of the Kalahari Desert, South Africa, as an arrow poison. The Trustees of the Museum have approved the purchase

for the Department of Geology of part of the skeleton of the horse like mammal *Moropus* This is one of the Chalicotheres, distantly related to the horses, which they resembled in their rather small head and long neck The fore limbs were long compared with the hind limbs, so as to give the trunk a giraffe like pose Like the horses, they were herbivorous, but they had claw like hoofs, three on each foot Chalicotheres have been obtained from early Tertiary times onwards, from Europe, Asia, Africa, and America Hitherto the Museum had only some incomplete remains from India, and a single claw from Central Africa The individual now acquired came from the Middle Tertiary of North America It stands as high as a large horse, but the bones are far more massive Recent additions to the mineral collection of the Museum include some crystallised sprays of native gold in calcite from Torquay, Devonshire, discovered and presented by Prof W T Gordon

Prof F O Bower, F R S, made "The Evolutionary Relation of the British Ferns" the subject of his presidential address to the Yorkshire Naturalists' Union at York on Dec 8 The address is published in full in the *Naturalist* for January 1929, and is of very great interest to British botanists, as the following citation will indicate "Having this year completed nearly half a century's research on 'Ferns,' and summed it up in three volumes in which the aim has been to reconstruct their chief evolutionary sequences upon a foundation of Organography, it seemed not inapt to use the present opportunity for placing our British Ferns in their probable relation to the Class at large I believe this has never yet been done" Both task and man were most apt to the occasion, a memorable one for the Union, a large meeting listened to a most delightful and stimulating address which did not restrict itself to the written word, but often diverged into a most interesting and relevant commentary upon the slides used in illustration, which were made from the plates of Sir William Hooker Prof Bower pointed out that in Great Britain we have only some forty species out of a total of 6000, but these are representative of half the families and about one eighth of the genera "This is probably the consequence of the position of Britain on the extreme fringe of a great continental area" Many of the largest fern genera are monotypic with us Prof Bower discussed this interesting fact, concluding that probably the majority of these British ferns "represent vestiges of a richer flora of the past, and that the species themselves have, by their more ready adaptation, or by more hardy constitution, been able to subsist in surroundings from which their congeners have retired beaten" "In fact, they symbolise the tenacious and adaptable race of men that inhabits these islands"

Prof J A Fleming gives interesting personal recollections of Sir Joseph Wilson Swan in the *Journal of the Institution of Electrical Engineers* for February in connexion with the invention of the carbon incandescent electric lamp In particular, he points out that one of the carbon incandescent lamps shown by Swan at an Exhibition in Newcastle on Tyne on Dec 18, 1878, is still preserved in the Science Museum at South Kensington It is necessary to distinguish between patent priority, which is often a mere matter of luck or promptitude, and that scientific or technical priority which is based upon achievements, exhibitions, public statements, or the evidence of contemporary workers Scarcely any invention springs into existence in full completion In many cases inventors may with justice claim to have originated some part of an invention It was thus with the invention of the electric lamp of small candle power The 'subdivision of the electric light' was the problem which the electricians of 1878 had to solve In 1879, Fleming was scientific adviser to the Edison Telephone Co, and in 1882 he was appointed in the same capacity to the Edison Electric Light Co and to the Edison and Swan Co In his opinion the credit for the epoch-making invention of the electric lamp cannot be solely attributed to T A Edison Sir Joseph Swan is, without doubt, one of those whose names are inscribed high up on the roll of fame For all future time his name will be connected with the invention of the carbon filament electric lamp

During the summer meeting last year at Glasgow of the Institution of Electrical Engineers, many members visited the works of the British Aluminium Co at Tulloch and Fort William The company has two hydro electric stations in operation, that at Foyers on Loch Ness, opened in 1896, and a second at Kinlochleven, on Loch Leven, opened in 1909, while a third and much larger one is being erected about a mile from Fort William This is not only of interest on account of its size and its various engineering features, but also as an example of the use of water power for manufacturing in a remote area dominated by the mountain Ben Nevis The most notable piece of construction has been the boring of the tunnel from the valve shaft at the Treig Dam to Fort William, 15 miles in length Commenced in the summer of 1926, the last shot opening the tunnel was fired on Feb 9, the work having proceeded from 23 faces by means of vertical shafts and horizontal adits From the surge chamber on the hill above Fort William the water will be conveyed by three steel pipes, at a maximum head of 800 ft, to the power house, which will eventually have turbines of a total capacity of 120,000 h p The catchment area is 303 square miles in extent, the rainfall over which varies from 50 inches per annum in the northern part to 160 inches on the summit of Ben Nevis A short description and a map of this important scheme was given in *Engineering* for July 6 of last year Though the tunnel is now bored, about half of it still remains to be lined with concrete

The Annual Summary of the World's Shipbuilding, issued by Lloyd's Register, is a statistical return of great value affording an indication of the progress of this great industry in all countries The summary for 1928 deals with the ships launched during the year, their tonnage, classes, types and machinery, and includes tables showing the tonnage launched for many

years back Shipbuilding is an industry liable to very great fluctuations, and one which, owing to the War, experienced great difficulties The fluctuations will probably always occur, for the demand for ships varies with many factors, but it is a satisfactory feature of last year's return to find that the tonnage launched in Great Britain and Ireland was 53 6 per cent of the world's tonnage of about 2,700,000 tons The tonnage launched in 1893 was about one million tons, in 1903 it rose to two million, in 1913 to three million, and in 1919 to more than seven million tons Of this seven million tons about half was built in the United States, but after 1921 shipbuilding in the United States sank to a much lower level, and last year the tonnage launched in that country amounted to only 86,000 tons The growth of the mercantile fleets of the world can be seen by comparing the total tonnage of 42,514,000 tons of 1914 with the 61,594,000 tons of 1928 Remarkable changes in ships have taken place also Oil tank ships in 1914 amounted to 1,479,000 tons, in 1928 to 6,544,000 tons , motor ships totalled 234,000 tons in 1914, and 5,432,000 tons in 1928 , while steamers fitted for burning oil totalled 1,310,000 tons in 1914 and 19,000,000 tons in 1928 The largest vessels launched during 1928 were the German Atlantic liners *Bremen* and *Europa*, of 46,000 tons each

WE have received the first number of the *Journal of Nutrition*, edited by J R Murlin, assisted by an editorial board of ten well known American experts in this branch of science It is to be published every two months by the American Institute of Nutrition, the president of which is E F Du Bois , at present one volume of about 500 pages will be issued each year The first number (September 1928) contains articles by H M Evans, "The Effect of Inadequate Vitamin B upon Sexual Physiology in the Male" and "Relation of Vitamin E to Growth and Vigour", by E V McCollum and collaborators, "The Distribution of Vitamin E" , by B Sure, "A Detailed Study of the Rôle of Vitamin B in Anorexia in the Albino Rat" , and by the editor, "Vital Economy in Human Food Production," etc , some of which we hope to refer to in more detail later The *Journal* is well got up, with a portrait of Lavoisier on the cover, and is clearly printed The science of nutrition has expanded so greatly in the last few years that there is undoubtedly room for another journal dealing solely with this subject , the composition of the editorial board should ensure that it maintains a high scientific outlook It can be obtained in Great Britain from Messrs Baillière, Tindall and Cox

AN article on the marine biological laboratory at Seto, Japan, its equipment and activities, with remarks on the fauna and flora of the environment, appears in the *Memoirs of the College of Science, Kyoto Imperial University*, Series B, vol 3, No 3 , 1927 The laboratory, which is affiliated to the departments of zoology and botany of Kyoto University, was opened in 1922 It consists of a number of separate buildings—an aquarium open to the public, a students' laboratory, two research laboratories, and a dormitory capable of accommodating thirty persons Up to-date equipment is installed throughout, and individual research rooms are furnished with electricity and running salt and fresh water For the collection of material the laboratory possesses, in addition to three rowing boats, one vessel of 19 tons capacity, fitted with masts and sails and equipped with a 25 h p semi Diesel gas engine Up to the present the staff has been engaged mainly in making faunistic surveys of the various collecting grounds A preliminary survey of the littoral and inshore areas has already been completed, but that of the deeper waters has not yet been fully worked out Spring and summer vacation courses —attendance at which is compulsory—are provided for students of biology at the University, and a summer course is also provided for teachers of biology in public schools

THE Report of the United States Coast and Geodetic Survey for the year ending June 30, 1928, in addition to the usual record of work, mentions several new features The demand of air maps has led to a new branch of the department's work Already several sheets of recognised flying routes have been published and others are in preparation A big development in this branch of survey work is anticipated In coast surveys considerable use is now being made of echo sounding with the fathometer, for which the claim is made that it allows work to be done twice as quickly as by any other means It is now used in eight survey vessels which can work at full speed, and stop only when temperatures or water samples are required In connexion with echo sounding, a further development is sound ranging in order to fix positions in thick weather The use of this method allows hydro graphical work to be continued almost regardless of weather conditions and throughout the twenty four hours The report gives a number of charts showing the state of field work up to the end of the year under consideration

THE recent series of illustrated post cards of British trees issued by the Natural History Museum, as F 22—F 28, contain excellent photographs and illus trations of trees, long familiar in Great Britain, if not necessarily native In each series two photographs show the appearance of a fine example of the tree in winter and in summer, whilst two more coloured illustrations depict and analyse flower and fruit These cards, with their accompanying descriptive leaflet, together with an exhibit of British grown trees in a bay in the Central Hall of the Natural History Museum at South Kensington, to which the leaflet refers the reader, should help to make the city dweller more alive to the beauty and interest of the trees of the countryside

APPLICATIONS for the Government Grant for scientific investigations must be made to the clerk to the Government Grant Committee, Royal Society, Burlington House, W 1, upon the requisite form, by Mar 31

DR KARL JORDAN, curator of the Entomological Department of the Zoological Museum at Tring, has been elected president of the International Commission

on Zoological Nomenclature in succession to Prof F C Monticelli, deceased Prof Filippo Silvestri, of Portico, Italy, has been elected a member of the Commission in succession to the late Prof F C Monticelli, of Naples

THE new year issue of *The Fight against Disease*, the organ of the Research Defence Society, reminds us that the Society has now been in existence for twenty one years An interesting correspondence between Lord Knutsford and the Hon Stephen Cole ridge on diabetes and insulin treatment appears in this number

A CATALOGUE issued by Mr Francis Edwards High Street, Marylebone, of books on the voyages of Captain James Cook, contains several items of great interest One entry is the original painting by J Webber who was artist in the *Resolution*, of the death of Captain Cook in Hawaii This picture is well known from the engraving by Bartolozzi Another item is the manu script log book of H Roberts, who as mate of the *Resolution* was in charge of the pinnace which took Captain Cook ashore for the last time The log runs from October 1778 to November 1779 when Capt King demanded for the Admiralty all log books and diaries kept on board the ship

APPLICATIONS are invited for the following appoint ments on or before the dates mentioned —An assist ant in the Electrical Engineering Department of the Coventry Municipal Technical College—The Director of Education, Council House, Coventry (Mar 8) A head of the Building Department of Rutherford Tech nical College, Newcastle upon Tyne—The Director of Education, Northumberland Road Newcastle upon Tyne (Mar 9) A head of the Engineering Depart ment of the Technical Institute, Gillingham—R L Wills, 15 New Road Avenue, Chatham (Mar 9) A woman lecturer in education in the Department of Education of the University of Bristol—The Secretary, Department of Education The University Bristol (Mar 11) A lecturer in engineering at the Tech nical College East London, South Africa—The High Commissioner for the Union of South Africa South Africa House, Trafalgar Square W C 2 (Mar 12) A Tancred student in physic at Gonville and Caius College, Cambridge—E T Gurdon 28 Lincoln s Inn Fields, W C 2 (Mar 12) A director for the Harcourt Butler Institute of Public Health Rangoon—The Secretary to the High Commissioner for India, General Department 42 Grosvenor Gardens S W 1 (Mar 13) A professor of botany in the University of Birmingham—The Registrar The University, Birmingham (Mar 16) A horticultural lecturer and adviser under the Bucks County Council—The Agricultural Organiser Education Sub Office, Aylesbury Bucks (Mar 16) A professor of philo sophy in the University of Lucknow—The Registrar The University Lucknow (Mar 17) An assistant lecturer in economics in the University College of North Wales The Registrar University College of North Wales Bangor (Mar 18) An assistant inspec tor in connexion with agricultural and horticultural education and research—The Secretary Ministry of Agriculture and Fisheries 10 Whitehall Place, S W 1 (Mar 18) A lecturer in metal mining in the Mining Department of the University of Birmingham—The Secretary The University Birmingham (Mar 23)

ERRATUM Obituary of Dr J W L Glaisher in NATURE of Jan 26 p 135 col 2 line 8 from bottom for 1910 read 1901

Our Astronomical Column

SPECTRA OF MINOR PLANETS —*Lick Observatory Bulletin*, No 407, contains an investigation of this subject by Mr N T Bobrovnikoff, he used a one prism spectrograph on the 36 inch refractor As might be expected, the light of the small planets is wholly reflected sunlight, there are no absorption bands as in the giant planets The violet and ultra violet regions are generally very weak as compared with the spectra of *G* type stars There is evidence of difference of composition of different planets, thus Ceres is bluer than Vesta, the maximum of intensity of the latter being much further towards the red end, the values given are Ceres, λ4800, Vesta, λ5300 It has been deduced both by changes of light and of spectrum that Vesta rotates in $5^h\,55^m$ The sugges tion is made in the article that minor planets may be comets that have lost their gaseous envelope, but it should be remembered that Halley's comet was in visible when in transit over the sun in May 1910, whereas any solid body of even a few miles in diameter would have been detected, the comet being near the earth

MAGNITUDES OF STARS IN THE CAPE ZONE CATA LOGUE —The importance of the accurate determina tion of magnitudes both for statistical purposes and for the deduction of spectroscopic parallaxes has been more fully realised during the last two decades The Cape Observatory has lately published a volume which gives the photographic magnitudes of 20,843 stars in the Cape Zones (Declination − 40° to − 50°) the Harvard spectral type and photometric and photographic magnitudes being given for comparison

Very careful experiments have been made at the Cape of the photographic effects of different exposures different intensities of light and different brands of plates Kron gave an exponential formula with different values of the exponents for different brands of plates This is adopted with the simplification that Kron s α_1 α_2 are each assumed equal to 0 25 for all brands of plates The quantity *I*, known as the optimal intensity, is, however, considerably greater in slow than in fast plates The mean difference (irrespective of sign) between Cape and Hertzsprung is 0 07 mag, the difference from Harvard for 16 stars in the south polar sequence is + 0 07 mag

The satisfactory conclusion is reached that if there is on a plate one star the magnitude of which is known from extraneous sources, the magnitudes of the other stars on the plate can be deduced The zero point of the Cape system was derived from the Harvard visual system corrected for colour There is found to be a marked tendency for the colour indices to group themselves round four maxima the positions of which are − 0 04 mag, + 0 38 mag, + 0 84 mag, + 1 30 mag It will be seen that they are nearly equally spaced

Research Items

DUGONG FISHING IN MADAGASCAR —M G Petit publishes in the *Bull et Mém Société d'Anthropologie de Paris*, T 8, Sér 7, fasc 4 5 6, some further observations on the ritual of dugong fishing in south west Madagascar Small light outriggers, extremely mobile, are employed, the fishermen being two in number to each, a harpooner who stands in the bow being in command Before setting out, the harpooner consults the *Sitily* as to whether conditions are favourable, and he is provided with a talisman (*Ody*) This is used first to consecrate a vessel of sea water, and is then placed in the prow and covered with a piece of old net to protect it The sea water is used to sprinkle the canoe, while invocations are addressed to it, and to the harpoon and its ropes It is also used to wash the head and hands of the fishermen As soon as the day for fishing has been fixed, the fishermen must abstain from all contact with their wives, and must not touch food prepared or water drawn by them The fishermen are in fact in a magical state, of which the serious nature is indicated by the fact that to miss the dugong not only entails misfortune for the village, but will be followed by the death of a member of the fishermen's family When the animal has been brought to land, its body is scrupulously hidden from the sight of women and children The body is dismembered by an old man, and the blood carefully collected and divided into three parts, one poured on the sand by the canoe, one into the sea, and the third smeared on the prow of the canoe the harpoon and the rope The flesh is eaten on the beach, first by men and, when they are satisfied, by women and children, but no knife, fork, or other utensil must be employed, nor must anyone spit or blow the nose The carcase must be buried, this being done with ceremony, as neither beast nor bird, but only man, must eat the flesh or pick the bones If the animal is female, connexion is enjoined on the fishermen, a custom which is found on the east African coast, and in a Chinese account of the Aino of Sakhalin in relation to women fish, presumably seals

THE STARLING IN THE UNITED STATES —The European starling, set free in New York in 1890 and 1891, has since 1910 spread rapidly throughout the United States, so that it seems likely to colonise all the country east of the Rocky Mountains, and, should it pass the Continental Divide, to prosper also on the Pacific coast With such an extension of range possible, it is important that the economic influence of the bird should be properly understood, and E R Kalmbach supplies the needed information in a U S Department of Agriculture *Farmer's Bulletin* (No 1571, December 1928) His conclusion is that most of the starling's habits are either beneficial to man or of a neutral nature Field observation has established the fact that the time spent by starlings in destroying crops or in molesting other species of birds is extremely short compared with the endless hours they spend searching for insects or feeding on wild fruits It is admitted that the bird damages cherries and certain other small fruits, and that its roosting habits make it objectionable in cities, but it is claimed that these are the results of overabundance rather than pronounced tendencies for harm on the part of the individual bird Such conditions are local and should be remedied by local control, such as the destruction of the roosts, or if that be not possible, by fumigation—a tricky and perhaps dangerous proceeding —or on a small scale by trapping

EVOLUTIONARY SIGNIFICANCE OF PARASITES — Prof R Hegner (*Quart Review Biol*, 3, 1928) discusses the protozoa found in man and in monkeys He states that of the four genera of amœbæ that live in man, three are represented in monkeys and the fourth has probably not yet been discovered on account of its rarity Four of the six well authenticated species of human amœbæ are indistinguishable from four of the species found in monkeys Among the intestinal flagellates of monkeys are five species that are indistinguishable from five of the seven species which live in man The ciliate *Balantidium coli* which lives in man is probably the same species that has been recorded from various species of monkey All three species of human trypanosomes seem to be present as natural parasites of monkeys, but the Leishmanias have not been reported from monkeys Malarial parasites that occur in monkeys resemble the three species that live in man Thus sixteen of the twenty five species of human protozoa have been described from monkeys One genus of ciliates (*Troglodytella*) and one *Babesia* occur in monkeys but not in man Comparison of human protozoa with those of mammals other than monkeys shows that they can be distinguished without difficulty, for example, the intestinal amœbæ and flagellates of the rat and the rat trypanosome are not identical with any species of human protozoa If the proposition is valid that close relationships of parasites indicate a common ancestry of their hosts, then the facts available furnish evidence of importance in favour of the hypothesis that monkeys and man are of common descent

FISH STATISTICS FROM LATVIA —The Section of Fish and Fisheries Industries of the Ministry of Agriculture has continued its fish statistics for 1927 in Latvia (*Bulletin statistique des pêches maritimes de Lettonie* Année 1927, Rédigé par V Miezis, Riga, 1928) The report is in Latvian and in French Tables are given relating to the various catches in the years 1924–27, for the months in 1927, giving the total weight in kilograms of the fish taken and their money value, the quantity of fish month by month in 1927 and according to districts, details of the boats and gear, number of fishing days, and the state of the fishing each month, also the number of seals killed is included (84 in 1927, mostly from the Kolkas region) At the end there is a useful list of the names of the fish in Latin, Latvian, French, German, and Russian Herring form the largest part of the fishery, then flat fish, salmon and salmon trout, cod and *Zoarces viviparus* being sometimes in greater numbers than the salmon Sprat and eels are also caught The herring fishery for 1927 is the largest of the four years, the other years in order being 1925, 1926 and 1924, the order for flat fishes and turbot is 1926, 1925, 1924 and 1927

HALOGEN COMPOUNDS AND TOAD TADPOLES —Mr Shinryo Ohfuchi describes the effect of chlorides, bromides, and iodides, and also of feeding with thyroid substance, on the toad *Bufo vulgaris formosus* ("Effect of Halogen Compounds on the Growth of the Tadpole of *Bufo vulgaris formosus* B" *Science Reports of the Tôhoku Imperial University*, 4th Series (Biology), Sendai, Japan, vol 3, No 4, Fasc 1, 1928) The halogen compounds, sodium and potassium chlorides, bromides, and iodides, were mixed with the pond water in bowls, and algæ were given in every vessel All the tadpoles were fed on cow's liver, except those fed on the thyroid extract Liver and each culture medium, with algæ, were renewed every day It was found that, in general, chlorides tend to accelerate the growth of the body at first, later to retard Bromides

retard at first, later accelerate. Iodides retard the growth of the trunk and hind limbs but tend to increase the tail dimensions, thus indicating a longer period during atrophy of the tail. Metamorphosis is hastened by feeding with extract of thyroid, but potassium iodide in the water does not have the same effect.

MOLLUSCA FROM NEW ZEALAND.—Mr. A. W. B. Powell in two papers describes three new volutes and five new land shells from New Zealand (*Proceedings of the New Zealand Institute*, vol. 59, Part 2, 1928). The larger recent volutes of New Zealand are separable into two main groups, one occurring in shallow and the other in deeper water. Two of the new species belong to the first group, the members of which show much variation and are characterised by a projecting callus plate on the columella, the deeper water species having none. The radula of the Volutidæ is of a simple degenerate type, but it is possible to detect slight differences in the single central tricuspid tooth which remains in nearly all species. These differences in shape of base and length of cusps help the author to separate the species, but as the teeth of the radulæ of other molluscs are known to be variable, it is well to be careful in attributing importance to these slight differences until many specimens have been examined. The land shells described in the second paper are interesting, but the shells only are described. *Murdochia aranea* is a beautiful little snail with delicate white riblets showing up on a reddish brown background. *Cavellia spelæa* is the largest species of the genus as yet found, measuring 5.25 mm. across. It is a sub-fossil species found in a cave together with *Moa* bones, and also with the common bush snail *Charopa coma*.

GROWTH REGULATING ACTION OF THE LEAF.—R. Dostál has of late years developed a theory as to the significance of the metabolism of the leaf as a correlating influence upon growth. Whilst some striking experiments have recently been described by this worker, in which the normal periodicity of scale and leaf production in the annual cycle of the leafy shoot of the tree has still been maintained under very exceptional external conditions, many of the experimental data which were associated with the development of this view will be found in a long paper published in the *Acta Soc. Scient. Nat. Moraviæ, Cechoslovakia*, 3, 83-210, 1926. In general, his view is that the growth of the axillary or terminal shoot primordium is very much influenced by the metabolism of the subtending leaf, and he examines the various marked changes in development of the shoot that follow upon mutilation or other experimental modification of the normal activity of this leaf. He also analyses, in experiments with *Circæa intermedia* and *Scrophularia nodosa*, the different morphogenetic quality of different regions of a shoot, as exemplified by the different results obtained when similar regeneration experiments are carried out with isolated nodes from different regions of the same shoot.

GRASS FIRES AND PLANT SUCCESSION IN SOUTH AFRICA.—During the present year the vegetation of South Africa will have, perhaps, a special interest to many readers of NATURE, and attention may be directed to the memoirs on the Botanical Survey of South Africa, which are being issued by the Department of Agriculture under the general direction of Dr. I. B. Pole Evans, Director of the Botanical Survey. *Memoir* No. 12, recently issued, by Ernest E. Galpin, upon the Springbok Flats, raises in an interesting manner one very controversial South African problem—the practical significance of annual burning of grassland. Galpin's conclusion is that acacia trees will gradually spread over the whole Springbok Flats, so that the grassland will become more or less dense acacia scrub. The cause of this change of vegetation is traced in a large measure to the suppression of the custom of annual veld burning, as European methods replace traditional native ones. The soil probably increases in humus with the suppression of the fires, but if the result is too intractable acacia scrub, it may be unfortunate, and the traditional native practice of burning thus prove to be justifiable. On the other hand, on the poorer grassland of the neighbouring veld, which stands higher than the rich loams and fertile grasslands, burning seems to be a very harmful practice. The wind then catches the exposed surface of the sandy soil and carries it forward, so that the sand veld is encroaching on the richer cultivable land as the result of frequent fires. Galpin has described a very interesting and rare new plant, *Cucumis humofructus*, Stent, which buries its fruit in the ground as it ripens as the result of negatively geotropic growth curvatures in the stalk.

CHLOROPHÆITE AND PALAGONITE.—The discussion of the nature of these and related mineraloids and of the terminology to be applied in specific cases, is continued by Martin A. Peacock and R. F. Fuller in the *American Mineralogist*, July 1928, and by L. L. Fermor in the *Rec. Geol. Surv. India*, Part 2, 1928. Dr. Fermor presents a general formula—

$$2\tfrac{1}{2}H_2O \cdot 5R_2O_3 \cdot 20SiO_2 + n(RO \cdot H_2O) + (80 - 4n)H_2O$$

—representing a series in which not only chlorophæite and palagonite find a place, but also certain other amorphous or micaceous minerals. The two other authors claim that ferric oxide is strongly dominant in chlorophæite, whereas alumina is abundant in palagonite. The former they regard as a result of hydrothermal action on basic constituents of basalts and dolerites, whereas palagonite is interpreted as a gel produced by the hydration of sideromelane. They propose that sideromelane should be retained as a specific name for clear, pale coloured basaltic glass as distinct from tachylyte, which is deep brown, opaque, and even microscopically turbid. Fermor, advocating the view that palagonite falls within the chlorophæite series, naturally points out that the term chlorophæite has twenty years' priority, and should therefore be adopted as the mineraloid name. Palagonite, he thinks, should be used as a rock name, and sideromelane he regards only as a variety of tachylyte. Much of the existing confusion doubtless arises as a consequence of basaltic alteration products and mesostatial material having been called palagonite when terms like chlorophæite and delessite would probably have been more appropriate. Chlorophæite, in the sense of Peacock and Fuller, is now a well established term, but palagonite can no longer be used without a careful explanation of what it is meant to imply.

ATMOSPHERIC OZONE.—The issue of the *Proceedings of the Royal Society* for Feb. 4 contains Dr. G. M. B. Dobson's third report of the work of himself and of his collaborators on the ozone of the atmosphere. In this they have been mainly concerned with the fluctuations of the ozone content in typical cyclones and anticyclones, and their extensive data are summarised in a convenient set of maps and tables which, apart from their intrinsic interest, should be of great value when they can be subjected to detailed analysis in conjunction with other meteorological records. Dr. Dobson has already found at least two important connexions with other phenomena. One of these, which was suspected previously, and has now been confirmed, is that there is a small but definite tendency for days with much ozone to be associated with

magnetically disturbed conditions The other has been found by studying the ozone records in relation to the movements of the large air masses, as diagnosed by the Norwegian Meteorological Institute It appears that polar air has a high ozone content and tropical air a low ozone content, and since the weather records are essentially obtained from data which refer to the troposphere whilst the centre of gravity of the ozone layer is probably at a height of from forty to fifty kilometres, the ozone measurements thus give evidence that the large tropical and polar air currents extend to a great height and bring their own stratosphere with them The study of cyclones and anticyclones has now been abandoned, as it is felt that further work in this field must be left to larger organisations, and the recording instruments have been sent to a number of scattered stations in the northern and southern hemispheres, in an attempt to find how the ozone varies over the surface of the earth

TWO MILLION VOLT BATTERY —At the Trafford High Voltage Laboratory of the Westinghouse International Co there is now in operation a two million volt battery which is used for testing the strings of insulators used for suspending the transmission lines on 220 kilovolt systems The pressure obtained is not an alternating pressure obtained by transformers but a unidirectional damped discharge Instead of using ten groups of condensers as was done last year, twenty are now used They are charged in parallel by means of large thermionic power tubes and discharged in series In order to measure the voltage, the spherical electrodes have each to be fifty nine inches in diameter The set is of great use in determining the performance of lightning arresters and in the design of cable and transformer insulation to withstand electric surges due to lightning or other causes The shape of the protective rings round the strings of insulators used on 220 kilovolt systems was determined by experiment, very definite results being obtained In addition to their electric tests, the strings of insulators are subjected to a mechanical tension of 20,000 lb A descriptive note of this battery is given in the *Westinghouse International Magazine* for February under the heading of the "World's Most Powerful Lightning Generator"

THE SHAPES OF MOLECULES —The effective area which a molecule presents to a slow electron depends very markedly on the relative velocity of the two particles, and it has now been shown conclusively that, quite apart from the excitation of quantum transitions, classical kinetic theory cannot account for the nature of the collisions, and fails in particular to explain the apparent transparency of many substances for very slow electrons In the first number of the new series of the *Annalen der Physik*, E Bruche has given a review of the results obtained up to the present in this field, including a description of his own recent work upon ammonia and water vapour The collected curves showing the molecular area as a function of the speeds of the incident electrons are very instructive, and exhibit regularities which indicate that the details of the collisions are determined both by the atomic constitution of a compound and by the structure of its outer shell of electrons Perhaps the most remarkable of these is the close correspondence between the curves for methane and for krypton Dr Langmuir and Prof A O Rankine had already commented upon this similarity in other connexions, and more recently it has been found that their ionisation potentials are also not much different, being 13 volts for the atom, and 14 6 volts for the molecule This resemblance to an inert gas evidently indicates that the molecule of methane possesses a high degree of symmetry, and, in the opinion of E Brüche, affords good evidence for the old model for methane in which the four hydrogen atoms were placed at the angular points of a regular tetrahedron, and the carbon atom at its centre

FIREDAMP EXPLOSIONS WITHIN CLOSED VESSELS —The Safety in Mines Research Board has previously studied the effects of firedamp explosions within closed vessels, such as the casings of electrical switch gear, but has now extended this investigation to explosions in vessels divided into intercommunicating compartments (S M R B, Paper No 49, by C S W Grice and R V Wheeler London H M Stationery Office) Beyling, in Germany, has shown that the ignition of an explosive mixture in one compartment may cause a considerable rise of pressure in another, and this result has been confirmed An explosion of a mixture of firedamp and air in a comparatively large volume and propagated through a narrow opening into a smaller compartment, may lead to the rapid development of a high pressure, and violent explosions can be caused in this way by even weak mixtures of methane and air Casings containing inter connected compartments are therefore unsuitable for use in mines

PROPERTIES OF BREEZE AND CLINKER AGGREGATES —Further work that has been carried out on breeze and clinker aggregates is described by F M Lea in *Bulletin of the Building Research Station*, No 5 (London H M Stationery Office) The properties of such aggregates are dependent upon the amount and nature of combustible material present Unburnt or partially burnt coal in breeze or clinker concrete is a frequent cause of failure, and the presence of only 4 per cent of coal may be responsible for serious damage The coal causes expansion of the concrete during setting and maturing, and ultimately cracking results Small quantities of sulphur do not appear to cause appreciable disintegration, although they may increase the rate of corrosion of reinforcement in the concrete The presence of dust in the aggregate results in a longer period of setting, since more water is required for mixing purposes, but does not cause subsequent unsoundness The *Bulletin* also describes methods of sampling and testing breeze and clinker aggregates in the field

THERMAL DECOMPOSITION OF AMMONIA —Baly and Duncan (1922) claimed that ammonia gas obtained by rapid evaporation of the liquid is less rapidly decomposed by a hot platinum wire than that produced by slow evaporation This effect was attributed to the existence of two kinds of molecules in equilibrium in liquid ammonia, all the molecules being assumed to pass into the form with the higher energy content on slow evaporation, while on rapid evaporation the equilibrium was supposed to persist in the gaseous state This work has been repeated by W A Stringfellow, who describes his results in the *Journal of the Chemical Society* for January These results do not confirm those of Baly and Duncan, practically no effect being observed in place of a 25 50 per cent decrease in reactivity with rapidly evaporated ammonia The addition of water vapour did not produce the great increase in decomposition observed in the earlier work Stringfellow suggests that as Baly and Duncan apparently did not exhaust their reaction vessel before filling it with ammonia, a rapid inflow of gas would not sweep out the air so completely as a slow stream The presence of adsorbed gases on the platinum wire might then account for the inhibition of the reaction observed when rapid evaporation took place The existence of different species of gaseous ammonia appears to be very unlikely

Cruise of the *Carnegie*.

THE non magnetic yacht *Carnegie*, which left Washington last May for a three year magnetic and electric survey of the oceans, has now completed the first unit of her voyage—that of encircling the North Atlantic In three letters to the Carnegie Institution of Washington (published by the Press Service Bureau), Captain Ault, who is in command both of the ship and of the Expedition describes the progress of the work so far accomplished The first place was Plymouth, reached only after encountering severe storms, then Hamburg, Iceland, Greenland, Newfoundland and Barbadoes Oct 9 was the date planned for arrival at Panama, and as these letters were being finished the ship was about 140 miles from that place, and the date was Oct 9, thus keeping well to the schedule

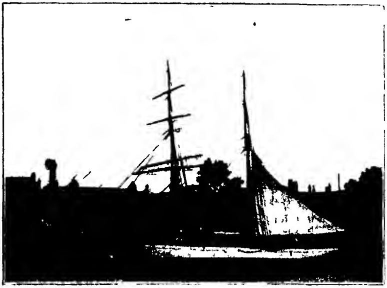

FIG 1—The *Carnegie* at Plymouth

The work is in full swing In this cruise a large amount of additional research in physical oceanography and biology is undertaken Every other day a magnetic station is occupied for compass declination, inclination, and horizontal intensity On alternate days an ocean station is occupied for water samples (salinity, hydrogen ion concentration, phosphate content, oxygen content) and temperature, with, occasionally, bottom samples and tow nets

The magnetic declination or compass variation at 135 stations has been determined, and the inclination and horizontal force at 49 stations, mostly near stations of former cruises Atmospheric electric observations have been made daily and many photographic records of continuous daily changes in the electric potential gradient also eight 24 hour series of observations of conductivity, ionic content and penetrating radiation Three hundred and thirty determinations of the depths of the sea have been made with the sonic depth finder This electrical apparatus for measuring the depth of the ocean floors records the time required for sound waves, from an oscillator mounted on the hull below the water line, to reach bottom and be reflected back to the surface Checks with the wire soundings show that the accuracy of the depth finder is within expected limits

For biological studies, tow nets at surface, 50 m and 100 m depth are taken, and the new Pettersson plankton pump, after several improvements, has been included as a regular instrument at each ocean station This is so arranged that it can be worked at a given depth by the release of a 'messenger,' the power being supplied by a 30 pound weight on the end of 100 m of wire wound on a reel on the pump 150 litres of water is strained through a small silk net attached to the pump When all the wire has run out the pump is closed off and hauled to the surface Salinities are now determined by means of the salinity bridge by the evening of the day on which the samples are taken Continuous records of both wet bulb and dry bulb temperatures or change of humidity at three positions have been secured The 'boom walk,' as used by Beebe (two 30 foot booms with net between extending from the ship's side), enables the naturalist to walk out over the water and use the dip net and tow nets outside the disturbances caused by the wash of the ship

On Aug 7 a station was occupied at the edge of the Grand Banks of Newfoundland in the cold Labrador Stream, which at that point had a depth of 130 m At the surface the temperature was 52° F, but at a depth of only 170 feet the thermometer fell to 34° Three days later in the Gulf Stream the water surface temperature was 79°F

Those who have seen the stores of spare apparatus on board have possibly marvelled at their numbers, careful provision fully justified when one realises the risk of loss every time an instrument is used One

FIG 2—Working the Pettersson plankton pump

such instance is recorded by Dr Ault, when a bottom sampler, eleven Nansen water bottles, and twenty two deep sea reversing thermometers were lost by the breaking of a wire about 2½ miles down

The *Carnegie* is happy in having contact by radio with America, England, France, Holland, and Germany

The Expansion of Telephone and Supply Systems.

THE problems that arise in connexion with the expansion of telephone systems are in some respects analogous to the corresponding problems in the supply of electric lighting. The Institution of Electrical Engineers therefore arranged on Jan 10 that papers on each of these subjects should be read at the same meeting so that the solutions adopted by the telephone engineers might be compared with those adopted by the supply engineers. The title given to each paper was "The Anticipation of Demand, and the Economic Selection, Provision, and Lay out of Plant"

Mr. J G Hines discussed the telephone system and Capt Donaldson the electric power system. The first problem that has to be solved in both systems is the forecasting of the probable number and distribution of subscribers that will exist in a given area at a given time. Once this is settled, the provision of a lay out which will ensure an efficient service at a minimum cost over this period is a technical problem which should admit of a rigorous mathematical solution

Secondary problems arise, however. In connexion with telephony there is the 'busy hour,' and in connexion with electric supply there is the 'peak load' In trunk line telephony the difficulty is sometimes met by having a special tariff so as to induce subscribers to communicate at the less busy hours, and occasionally, in electric supply, by means of meters which register more rapidly at stated times. There are many points of dissimilarity between the two problems. When a house has been wired for the electric light, it is most probable that there will be always a user in that house. In the case of telephone supply, especially in private dwellings, a change of occupier usually results in the telephone circuit serving the premises being given up. This involves recovery of the apparatus and the temporary or permanent abandonment of all the internal wiring which is always provided by the Post Office

In large cities high class property is often found next door to poor dwellings. Before the period covered by the Post Office forecast has expired, the smaller properties may be pulled down and replaced by blocks of flats or business premises, each requiring many telephones. It is necessary, therefore, to make detailed inquiries about possible alterations to property. Certain businesses like stockbroking and book making are very fluctuating. When there is a rush of work the number of telephones may be increased five times, and then when the depression comes they are given up

The data given show why overhead transmission is desired by engineers. A wire made of cadmium copper and weighing 40 lb per mile used overhead has a speech transmission efficiency equal to that of a 200 lb per mile underground cable. Public authorities, however, are increasingly reluctant to give permission to erect poles in public footways. Capt Donaldson said that the telephone problem is the more difficult, because each consumer must have his own individual pair of wires at least so far as the first telephone exchange

If the electric lighting stations built twenty five years ago had been ten times larger, it would have been in the country's interest. The replacement of reciprocating engines by the turbine has made it possible to accommodate considerably larger units of supply in the original engine rooms, but in many cases considerable alterations have had to be made. Capt Donaldson pointed out the fallacy of always replacing an engine by one of double the size, it is always necessary to assume that one engine may be out of commission. Hence the maximum reserve of power is obtained when all the engines are of equal size. The general situation is rapidly passing out of the hands of the smaller undertakers. Power engineers by careful study of the yearly loads can make reasonably accurate forecasts of the demand for some years in advance

The Rubber Research Institute of Malaya

THE first issue of the *Quarterly Journal of the Rubber Research Institute of Malaya*, Kuala Lumpur, January 1929, bears witness to the very active steps that have been taken to put the new Research Institute into working order. The director, Dr G Bryce, arrived in Malaya to take up his duties in September 1926. Some local appointments were made during the autumn of that year, and the other officers of the station were gradually brought in during 1927 and 1928, the seventeenth appointment being made in November 1928. By June 1927 the heads of the chemical, pathological, botanical, and soils divisions of the Institute were appointed, and engaged in visiting the neighbouring rubber research stations in Sumatra and Java. Temporary laboratory accommodation was provided by adapting a bungalow, and four months after the arrival of the heads of divisions in Malaya they had presented programmes of work for their respective divisions for the consideration of the Board of Control

In this first issue of the *Quarterly Journal*, brief summaries of the work of the different divisions are given, for the period up to Sept 30, 1928. These show that the officers appointed have lost no time in grappling with the many sided problems presented by the commercial cultivation of the rubber plant, and the preparation of the latex for market

The bulk of the journal consists of articles by various officers of the Institute upon many of the interesting problems that arise in connexion with research upon the growing and preparation of rubber. Besides being of interest to the rubber planters, many of these articles have special interest to botanists, colloid chemists, and other investigators of agricultural and industrial problems, who are not directly concerned with the rubber industry. Occasionally, however, a certain obscurity of expression makes some of these articles difficult to follow and particularly if the Research Institute wishes to carry interested growers with it in its investigations through the medium of its journal, it would seem worth while to expend more time and trouble upon the form in which these investigations, often themselves of great intrinsic interest, are described in print

Dr Haines discusses a topic of very general interest in countries with a tropical rainfall when he reviews the pros and cons of methods of silt pitting as a means of defence against excessive soil erosion. Experience which this investigator obtained in the classic experimental fields of Rothamsted is here utilised to visualise a soil problem specially characteristic of tropical and sub tropical conditions. The botanical division reports much active work upon vegetative propagation. Mr Mann, fresh from his contact with methods of

fruit culture at the Experimental Station at Long Ashton, near Bristol, discusses the conditions governing successful bud unions in Malaya, where vigorous growth of shoot and scion at the time of union, together with fair humidity in the weeks following the budding operation, seem the most essential conditions for success

Messrs A R Sanderson and H Sutcliffe give an account of some very valuable selection work on rubber they have had in progress before the formation of the Institute These experiments confirm the general impression that the selection of high yielding stock on any other basis than the yield of dry rubber over a long period of tapping, can, as yet, only be made with considerable uncertainty

The creation and propagation of high yielding strains —which Dr Weir, the head of the pathological division, reminds the reader may be at any time required endowed with resistance to some newly introduced pathogen, such as the South American leaf blight, which Dr Weir has studied in its native habitat—can obviously not be neglected by the Rubber Research Institute Mr Morris states that during a season's observations no pollen carrying insect has been seen to visit the female flowers of *Hevea*, which, it must be remembered, is not of Malayan origin, but an introduced plant isolated from its normal insect visitors Artificial pollination is successful between various selected clones, and a few seedlings have thus been obtained for further trial, but self pollination within the clone is usually negative in result The further analysis of the conditions, both internal and external, that contribute to successful pollination and fertilisation, is a promising field of investigation

Many other points of detail as to the chemical properties of the rubber, its preparation and various commercial defects, diseases of cover crops, of young, budded plants, etc , are dealt with in this first number of the new journal There is no doubt that if this standard is maintained the *Quarterly Journal* of the new Rubber Research Institute will be a publication of permanent scientific value

Association of Technical Institutions

THE annual general meeting of the Association of Technical Institutions was held in the Grocers' Hall, London, on Feb 22 and 23 As is customary, the installation of the president took place at the opening session, and, distinguished as have been the occupiers of the presidential chair in the past, the new president, Sir J E Kynaston Studd, is one of whom the Association may be justly proud By a happy chance, the year of his presidency coincides with his year of office as Lord Mayor of London But it is not only the civic honours that are his which distinguish him in and qualify him for his new office For some years now his activities in connexion with the Regent Street Polytechnic, of which he is president, have been well known

Since he was therefore in a position to speak to the Association as an expert, Sir Kynaston Studd's presidential address was expected to be one of unusual authority Nor was his audience disappointed His review of the work of such recent committees as the Balfour Committee on Trade, the Malcolm Committee on Education and Industry, and the Emmott inquiry into technical education and industry, was broad and illuminating The conclusion he drew from the reports of these committees may be summarised by saying that, although the Board of Education is now in a position as a result of the work done to do much to help technical education to attain the greater place it merits in our system, a great deal of the task of getting industry to come more and more to the technical college for informed help must be borne by such associations as the A T I In connexion with all this, he did not attempt to minimise the work done by the Atholl Committee on Examinations, but it was clear that he was closely in touch with the views of the majority of those engaged in technical education when he suggested that examinations are the least important part of the work of technical education We were glad, too, to note that he pressed home a vital point to which attention has already been directed in these columns (see NATURE, Nov 12, 1927, p 681, and July 28, 1928, p 121)—the status of the craftsman must be equal to that of any other worker, an end which will be difficult to attain unless industry is prepared to guarantee the same conditions of permanency to craftsmen as it does to clerks and others of the administrative staffs

Papers read and discussed during the meetings included "Broadcasting and its Relation to Further Education," by Mr C A Siepmann, of the B B C "Industrial Safety," by Sir Gerald Bellhouse, H.M Chief Inspector of Factories, and "Technical Training for Women," by Miss E E Cox, of the L C C Barrett Street Trade School

In connexion with the paper on industrial safety, a visit was arranged to the Home Office Industrial Museum, where safety devices are set out in admirable fashion Few people, as Sir Gerald Bellhouse pointed out in his paper, realise how big a toll accidents make upon industry Yet the most recent figures show that 156,974 accidents (of which 973 were fatal) were reported during 1927 to the Factory Department Out of these cases, those which come within the Factory and Workshop Acts mean that each year about £2,500,000 is paid in compensation additional administrative, legal and medical costs must bring the figure to not less than £5,000,000 per annum Statistics such as these should in themselves be sufficient to make employers, employees, staffs, and students of engineering schools in universities and technical colleges desire to visit the Home Office Industrial Museum, where may be seen all the best methods of preventing danger to life and limb which have become incidental to industrial processes

University and Educational Intelligence

CAMBRIDGE —Mr E N Willmer has been appointed University lecturer in physiology

The following grants have been made from the Balfour Fund £100 to Dr C M Yonge, for researches at Honolulu and elsewhere in reference to his experiments on the Great Barrier Reef, £50 to Mr F S Russell, for researches on the plankton of the Great Barrier Reef region

Birbal Sahni, Emmanuel College, has been approved for the degree of doctor of science

LEEDS —Mr F J Dent has been appointed gas research chemist in the Department of Coal Gas and Fuel Industries in succession to Dr A Parker, who has resigned in order to take up a responsible post with the Water Pollution Section of the Department of Scientific and Industrial Research Mr Dent has been working in the Department under Prof J W Cobb for the past two years upon the gasification of special cokes in oxygen, and upon heat treatment in hydrocarbon and other gases as a factor influencing the reactivity of coke

London —An offer by the trustees of the late Mr C H Clark of a sum of £10,000 for the establishment of a lectureship in the history and progress of preventive medicine and tropical hygiene has been accepted The Prime Minister has forwarded a grant of £1000 from the Beaverbrook Fund for Medical Research, to be applied to the purposes of, and administered under, the scheme for the Thomas Smythe Hughes Medical Research Fund

Dr T G Hill, reader in plant physiology at University College has been appointed to the University chair of plant physiology, tenable at University College, as from Aug 1 next He is the author (with Dr P Haas) of "An Introduction to the Chemistry of Plant Products" (1913), and of numerous papers on the structure and development of the higher plants, oxidative processes, etc, in botanical and other journals

Dr E J Salisbury, reader in plant ecology, has been appointed to the Quain chair of botany, tenable at University College, as from Aug 1 next His recent publications include papers on the influence of earth worms on soil reaction, geographical distribution of plants, and the causes and ecological significance of stomatal frequency

Prof W E Le Gros Clark, professor of anatomy at St Bartholomew's Hospital Medical College, has been appointed as from Sept 1 next to the University chair of anatomy tenable at St Thomas's Hospital Medical School

Sir John Dewrance, Prof W T Gordon, Dame Helen Gwynne Vaughan, and Sir John Snell are among the recently appointed fellows of King's College

Oxford —All Oxford men who have worked in the University Museum will be gratified that the degree of M A *honoris causa* has been conferred on Alfred Robinson, assistant to the secretary to the curators, and a well known figure to all science students in Oxford for the last fifty years

At a forthcoming meeting of Congregation, decrees will be proposed expressing the gratitude of the University (1) for the gift, received through the Prime Minister, of £1000 from Lord Beaverbrook for the furtherance of medical knowledge, and (2) for the bequest by the late Prof A W Scott of £4322 to be applied for the furtherance of physical science

Sheffield —Applications are invited for an Ironmongers' Company Research fellowship, value £500, and for two Ironmongers' Company Research Scholarships, each of the value of £150, particulars of which can be obtained from the Registrar, The University, Sheffield The latest date for the receipt of applications is April 1

Wales —Applications are invited from graduates of the University of Wales for five fellowships, each of the annual value of £200 and tenable for two years The applications must be received not later than June 1, by the Registrar, University Registry, Cathays Park, Cardiff

---

The New York correspondent of the *Times* has announced three important gifts for education in the United States North Western University is to receive about £1,600,000 under the will of Mr Milton H Wilson, New York University has received an unrestricted endowment of £200,000 from Mr and Mrs Percy S Straus, and Newhaven Hospital, which is affiliated to the Yale School of Medicine, has received £400,000 from the General Education Board of New York City, to be devoted to a new laboratory and dispensary and a service unit

Calendar of Patent Records

March 4, 1633 —On Mar 4, 1633, Richard Delamain petitioned Charles I that, in accordance with a promise given by the king two years earlier, he might have the sole making of a "mathematical instrument extracted from the logarithms and projected in circles for the speedy operating of mathematical practices" The petition passed the Signet Office on the same day, but no patent is enrolled, and it is uncertain whether this first patent for a slide rule was ever actually issued Delamain was not the first inventor of the slide rule The credit for this belongs to William Oughtred, who, according to his friend and translator, William Forster, had invented the instrument some years before and had not published the invention because ' it is a preposterous course of vulgar teachers to begin with instruments, and so instead of artists to make their scholars only doers of tricks and as it were juglers, to the despite of art, losse of precious time, and betraying of willing and industrious wits unto ignorance and idleness "

March 5, 1825 —On this date there was granted to W H James, one of the pioneers of railway transportation, a patent for a system of train propulsion in which all the axles throughout the train were driving axles, longitudinal shafts on the carriages operating the wheels through bevel gearing and being connected to each other by universal couplings the front shaft being driven by a steam engine or other agent An experimental line was laid down on which inclines of 1 in 12 were successfully negotiated, but the system was never adopted on the railways of Great Britain

March 6, 1648 —During the last few years of Charles I the ordinary machinery of granting patents broke down, and there are no entries in the printed indexes for the period 1642–49 The patent granted to Sir William Petty on Mar 6, 1848, for his invention of double and multiple writing, was issued by the authority of an ordinance of the "Lords and Commons assembled in Parliament," which formed the warrant to the Solicitor General and to the Commissioners of the Great Seal Petty seems to have had some difficulty in securing the adoption of the invention, for in the following year Parliament is petitioned by one Henry Morris to grant Petty and Morris "either a tax of *2d* a ream on paper, or *2s 2d* on 60 skins of parchment for a few years, or else £1500 or £2000 down for their services, or some good office"

March 6, 1916 —Rustless steel first attracted public attention when stainless table cutlery was introduced in 1914, though the importance of chrome and of nickel alloys had long been recognised The remarkable properties of high chromium iron were, however, not fully realised until the researches of Harry Brearley of Sheffield, which resulted in the production of a steel containing between 9 and 16 per cent chromium and not more than 0 7 per cent carbon, which was practically untarnishable and could be forged, rolled, hardened, and tempered, under commercial conditions Brearley's discovery was published before a British patent was applied for, but he obtained patents in Canada and the United States, the application in the latter country being filed on Mar 6, 1916

March 8, 1859 —A satisfactory cotton harvesting machine has yet to be discovered, and most of the world's cotton is still picked by hand, but of the many attempts to solve the problem, the pneumatic picker has had the greatest amount of success The first patent for a pneumatic harvester was granted in the United States to John Griffin on Mar 8, 1859, steam being employed to produce the vacuum

Societies and Academies

LONDON

Royal Society, Feb 21 —**P Kapitza** The change in electrical conductivity in strong electric fields (Parts 1 and 2) The change of resistance in a transverse field at temperatures of room, of solid carbon dioxide and ether, and of liquid nitrogen, has been studied in many metals It follows the same law in all of them The formula obtained gives a square law in weak fields and a linear law in stronger fields Change of resistance follows a linear law with increasing field, but in weak fields it is masked by disturbances existing in the metal equivalent to an internal magnetic field This additional resistance is independent of temperature, while the ideal resistance has a constant value for a given temperature for each metal, independent of its physical and chemical state The additional resistance is identical with the residual resistance which is observed at very low temperatures Supraconductivity is a general phenomenon in all metals, but is masked by additional resistance, which disappears at very low temperature in certain metals —**R R Nimmo** and **N Feather** An investigation of the ranges of the long range α particles from thorium C' and radium C, using an expansion chamber 'Extrapolated' ranges 9 90 and 11 70 cm in standard air were obtained for the long range α particles from thorium C in the ratio of 1 5 1 541 particles have been observed belonging to these groups In addition, 9 had ranges between 12 5 cm and 17 cm, and 13 had longer ranges The range of the most abundant group of long range α particles from radium C was measured as 9 16 cm, it is likely that there are others with ranges 8 1 cm 10 0 cm, and 11 0 cm respectively Nearly 500 long range particles from radium C were recorded —**C R Burch** Some experiments on vacuum distillation The method of evaporative distillation can be applied to the derivatives of petroleum An elementary kind of fractionation is possible Petroleum derivatives of exceedingly low vapour pressure can be prepared —**E C C Baly** and **N R Hood** The photosynthesis of naturally occurring compounds (4) —**B W Currie** and **R Alty** Adsorption at a water surface (1) —**W G Palmer** Some adsorption isothermals for a plane platinum surface —**B Lambert** and **A M Clark** Studies in gas solid equilibria —**G C Laurence** Relative velocities of the alpha particles emitted by certain radioactive elements —**H W Thomson** and **C N Hinshelwood** The mechanism of the homogeneous combination of hydrogen and oxygen —**E G Dymond** and **E E Watson** Electron scattering in helium —**E T Hanson** Diffraction and resonance —**S Goldstein** (*a*) The forces on a solid body moving through viscous fluid (*b*) The steady flow of viscous fluid past a fixed spherical obstacle at small Reynolds' numbers Oseen's equations for the flow of a viscous fluid at small Reynolds' numbers past a fixed spherical obstacle are solved completely, and a table given of the resulting values of the drag coefficient —**J Taylor** On the chemical interaction of ions, and the 'clean up' of gases at glass surfaces under the influence of the electrical discharge —**H M Macdonald** The total reflection of electric waves at the interface between two media —**L Hartshorn** and **D A Oliver** On the measurements of the dielectric constants of liquids, with a determination of the dielectric constant of benzene An accuracy of 1 in 10,000 is obtained, using a capacity method The method requires a comparatively large volume of liquid For very pure liquids in small quantities, a comparison method is used The dielectric constant of benzene is 2 2825 at 20° C, with a probable error of ± 2 parts in 10,000, mainly due to difficulties of obtaining a sample absolutely free from water —**J W Fisher** The wave equation in five dimensions —**E Griffiths** and **J H Awbery** Measurements of flame temperatures —**K Lonsdale** The structure of the benzene ring in $C_6(CH_3)_6$ The benzene ring in this compound is similar in shape and size to the six carbon ring in graphite, the nuclear carbons having a diameter of 1 42 A Three of the valencies of aromatic carbon are co planar, the ring itself and all the side chain carbon atoms lying in the (001) cleavage plane The puckered or 'diamond' type of benzene ring, and Morse's model are inadmissible

Geological Society, Feb 6 —**E St J Burton** The horizons of Bryozoa (Polyzoa) in the Upper Eocene beds of Hampshire Special horizons on which an abundance or deficiency of bryozoan remains occur are indicated within the three divisions of the Barton Beds (Lower, Middle, and Upper Barton) A recurrent facies of sedimentation may be coincident with the reappearance of species on higher horizons in the series —**M Black** The upper estuarine series of Yorkshire The Estuarine Series of Yorkshire is of deltaic rather than estuarine origin, and bears a close resemblance to the Coal Measures The Upper Estuarine Series is best exposed in the coast section between Gristhorpe and Cloughton (Yorkshire), where the sequence can be made out It is possible to distinguish between autochthonous plant beds and allochthonous, or drifted, ones The former are rare in the Upper Estuarine Series The drifted plant beds are much better developed Among these, a definite relationship exists between the type of sediment and the flora which it encloses The plant fragments seem to have behaved as a sediment transported by the water of the distributaries

Society of Public Analysts, Feb 6 —**T P Hilditch** and **Eveline E Jones** The fatty acids and component glycerides of some New Zealand butters The procedure consisted in oxidising the butter fat by means of permanganate under conditions in which all unsaturated components were transformed into acidic products, whilst glycerides containing only saturated fatty acids remained unaltered These fatty acids were recovered and their composition determined —**A Scott Dodd** A new test for boric acid and borates The pink coloration produced by adding mannitol and methyl red or sofnol indicator No 1 to a neutral solution is characteristic of boric acid, a distinct reaction being obtained with so little as 0 2 mgm The only substances causing any interference with the distinctness of the reaction are phosphates, arsenates, chromates, and tungstates, which make it difficult to ascertain the exact point of neutrality —**B E Dixon** The determination of small quantities of beryllium in rocks The chief obstacle to the accurate determination of small quantities of beryllium in silicate rocks is the difficulty of separating it from titanium This difficulty has been overcome by the use of *p* chloroaniline, which will precipitate titanium completely

DUBLIN

Royal Dublin Society, Jan 22 —**W R G Atkins** and **H H Poole** The photoelectric measurement of the illumination in buildings The vertical illumination was measured simultaneously in an exposed position and in the building The percentage ratio when the sun is obscured is called the 'daylight factor' A dwelling house and an old church were examined The illumination in the former was less than 1 per cent

in most places, rising to 7 per cent just inside large windows, or 14 per cent with the photometer sloped towards the light The factor in the church varied from 0 02 to 0 86 per cent, or, with sloped photometer, from 0 03 to 1 85 per cent It seems to be futile to use special glass, transparent to ultra violet light, in the usual type of dwelling house in windows which do not, at some time of the day, receive direct sunlight —**H H Poole** A modified form of radium emanation apparatus The apparatus in use in the Irish Radium Institute for pumping off emanation and drawing it into capillary tubes for therapeutic purposes has been modified so as to render its action more automatic, thus reducing the exposure of the operator to the radiations, and enabling the work to be carried on by a succession of less highly skilled workers than were required with the apparatus in its old form

Royal Irish Academy, Jan 28 —**P J Nolan** and **C O'Brolchain** Recombination of ions in atmospheric air (Part 1) Investigation of the decay coefficient by Schweidler's method The linear recombination law for small ions in atmospheric air is verified The recombination coefficient between small ions and nuclei is not constant The variation does not appear to be connected with the concentration of dust particles in the air —**P J Nolan** Recombination of ions in atmospheric air (Part 2) The law of recombination of ions and nuclei The relation between the rate of production of ions in atmospheric air and the equilibrium concentrations of small ions and nuclei is best represented by the equation $q = an^2 + \zeta n\sqrt{N}$ where $\zeta = 55 \times 10^{-6}$ The results of field observations generally support the proposed equation

EDINBURGH

Royal Society, Feb 4 —**N B Eales** The anatomy of a fœtal African elephant, *Elephas africanus* (*Loxodonta africana*) (Part 3) The contents of the thorax and abdomen, and the skeleton A detailed specification of the Proboscidea is given, anatomical differences between *Elephas* and *Loxodonta* are noted, and the relationships between the Proboscidea and other orders of mammals are discussed The group has numerous features of a primitive nature, in which it exhibits resemblances with the Rodentia, Sirenia, Hyracoidea and the Primates The nearest relatives were the ancestors of the modern Sirenians —**A D B Smith** and **J R Brown** Rôle of inbreeding in the development of the Jersey breed of cattle Inbreeding has played a small part in the construction of the breed in England Sewall Wright's coefficient now stands at only 3 9 + 0 3 as compared to the Clydesdale breed of horses with 6 and Shorthorn cattle with 26 Cows with annual lactations of more than 1000 gallons in less than a year are significantly less inbred, having a coefficient of only 1 85 Possible reasons are (1) miscellaneous inbreeding does not produce good results in yield, (2) heterosis between two strains, (3) inheritance of milk yield may not be in a common autosomal manner, but may be sex linked, in which case only certain types of inbreeding would be effective —**A W Greenwood** and **J S S Blyth** An experimental analysis of the plumage of the brown Leghorn fowl Whereas the plumage typical of the male is developed independently of the gonad and depends for its maintenance on a certain level of thyroid functioning, both gonad and thyroid play a part in regard to that of the female the former stimulates the latter to a higher level of activity than that present in the male and so indirectly causes a hyperthyroid effect on the feathers At the same time it modifies this condition by acting directly on the feathers and restricting the deposition of melanin into pencillings —**C W Stump** A human blastocyst *in situ* The blastocyst was obtained from the body of a woman aged forty six years It was fixed the day after the death of the mother, who was killed by a motor car accident, but was slightly injured Examination of the sections of the blastocyst and of the reconstructions made from the sections, place it in Bryce's group *D* of human blastocysts, which, now, with the addition of this new specimen, named H 381, and Stieve's Hugo specimen, includes thirteen blastocysts of relatively similar age

GENEVA

Society of Physics and Natural History, Dec 6 —**Rolin Wavre** The formula of Clairaut relative to geodesy The author obtains Clairaut's formula by a method much simpler than those hitherto given His calculation has the double advantage of not requiring the use of spherical functions and of making an approximation only at the last stage of the new and rigorous formulæ —**Pierre Dive** Internal movements of the terrestrial fluid The author applies the formulæ recently established by him, on the laws of rotation of a heterogeneous fluid with a density increasing with the depth, to the case of the earth Geophysicists admit that the continents should be considered as a light scoria floating on a denser viscous mass The calculations of M Dive give increases of velocity at a depth of 100 kilometres of 5 3, 7, 8 6, 9 5 cm per second for surface densities of 3, 2 6, 2 5, 2 4 respectively Of two continental masses floating in the viscous under layer, the larger and more deeply submerged will be carried towards the east with a greater velocity This movement is certainly much reduced by the viscosity, not taken into account in the calculations This calculation gives a concrete and simple explanation of the tangential force which geologists have long considered as the principal factor in the deformations of the solid part of the globe —**Adrien Jayet** The age of the lower portion of the sub lithographic limestones of the calcareous Alps of Haute Savoie The lower part of these limestones, styled Senonian in the explanation of the geological map of France (1/80,000), merge laterally into fossil bearing Cenomanian layers Hence there is not, at the point where the latter are missing in the series, an interruption in the series It is a matter of a lateral change of facies in a continuous sedimentary series

VIENNA

Academy of Sciences, Nov 16 —**J E Hibsch** The geological age of the sands and sandstones of the Bohemian Mittelgebirge, hitherto held to be Middle Oligocene —**K Menge** (1) A theorem on the length of an arc —(2) The general separation theorem

Nov 22 —**W J Müller** and **O Löwy** The theory of passivity phenomena (4) The dependence of the specific time of passivation for iron on the concentration and nature of the electrolyte —**R Dworzak** and **T Lasch** Cyclo acetals —**F Heritsch** *Michelinia Abichi* from the upper carboniferous of Nassfeld in the Carnic Alps —**D Poerner-Patzelt** and **A Pischinger** The behaviour of the structures of striated muscle fibres towards acids Muscles of various sorts were used in acetate–acetic acid buffers and with known hydrogen ion content and afterwards examined microscopically —**K Przibram** A colour change by pressure (piezochromy) in fluorite Green fluorite powdered and then compressed at 10,000 kgm per sq cm becomes violet —**L Kober** Mesozoic breccias in the upper schist cap of the Sonnblick and Glockner group

Diary of Societies

FRIDAY MARCH 1

ROYAL SOCIETY OF MEDICINE (Otology Section) at 10 30 A.M —J S Fraser and E D D Davis Discussion on The Acute Ear Microtia and Atresia of the External Meatus

ROYAL SOCIETY OF MEDICINE (Laryngology Section) at 5

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group) at 7 —Informal Meeting

SOCIETY OF CHEMICAL INDUSTRY (*Manchester* Section) (at Engineers Club Manchester) at 7 —Prof T P Hilditch Recent Advances in our Knowledge of the Structure of the More Common Fats

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section) at 7 —W Lawson The Rotor Bearings of Electricity Meters

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Informal Meeting) (at Newcastle upon Tyne) at 7 15 —Sir Joseph Isherwood Bart. and others Do the Rules of Classification Societies tend to improve Shipbuilding and Engineering in this Country?

GEOLOGISTS ASSOCIATION (at University College), at 7 30 —S E Hollingworth Evolution of the Eden Drainage in the South and West —M Chatterjee The Accessory Minerals in the Bodmin Moor Granite

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7 30 —L S Atkinson The Control of Electric Lifts

INSTITUTION OF AUTOMOBILE ENGINEERS (Graduates Meeting) (at 51 West Regent Street Glasgow), at 8 —E C Philbrow Inspection

ROYAL SOCIETY OF MEDICINE (Anaesthetics Section) at 8 30 —Dr G M Slot Deaths under Anaesthetics with Special Reference to their Pathology

ROYAL INSTITUTION OF GREAT BRITAIN at 9 —Sir Robert Robertson Infra Red Spectra

ELECTROPLATERS AND DEPOSITORS TECHNICAL SOCIETY (Birmingham) Conference on Chromium Plating)

SATURDAY MARCH 2

ROYAL INSTITUTION OF GREAT BRITAIN, at 3 —Sir Ernest Rutherford Molecular Motions in Rarefied Gases (I).

MONDAY, MARCH 4

ROYAL SOCIETY EDINBURGH at 4 30 —Prof Hans Przibram Quanta in Biology

VICTORIA INSTITUTE (at Central Buildings Westminster) at 4 30 —Dr A R Short Recent Literature concerning the Origin of Species

ROYAL INSTITUTION OF GREAT BRITAIN at 5 —General Meeting

SOCIETY OF ENGINEERS (at Geological Society) at 6 —H R Lordly The Waterproofing of Concrete Structures

INSTITUTION OF AUTOMOBILE ENGINEERS (Western Centre) (at Merchant Venturers Technical College, Bristol) at 6.45 —A H R Fedden Air cooled Engine Repairs and Layout

INSTITUTION OF AUTOMOBILE ENGINEERS (Graduates Meeting) (at Loughborough College) at 7 —G I B Hall Lubrication

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7 —L J Hunt and others Discussion on Variable-Speed Alternating-Current Motors

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Birmingham University), at 7 —Capt. J M Donaldson (Power Systems) J G Hines (Telephone Systems), and others Discussion on The Anticipation of Demand and the Economic Selection Provision and Layout of Plant.

HUNTERIAN SOCIETY OF LONDON at 7 30 —Prof A W Sheen Some Aspects of the Surgery of the Spleen (Hunterian Oration)

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8 —Dr L Hill Modern Methods of Heating and Ventilation

ROYAL SOCIETY OF ARTS, at 8.—Sir Thomas M Legge Thirty Years Experience of Industrial Maladies (Shaw Lectures) (III).

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society) at 8.—Prof A. R Ling Recent Advances in the Chemistry of Polysaccharides and Allied Compounds.

SURVEYORS INSTITUTION at 8.—F L. Thompson Recent Developments in Town Planning

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8 30.—Mrs. Gordon Gallien, J W Cornwall, and C C Rose The Kalambo River and Falls

TUESDAY, MARCH 5

ROYAL COLLEGE OF PHYSICIANS OF LONDON at 5—Dr J G Forbes Past and Present Diphtheria in England and Wales, with Special Reference to the London Metropolis (III)

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15—Prof. J S. Huxley Evolution and the Problem of Species (VI).

ZOOLOGICAL SOCIETY OF LONDON, at 5 30—B N Schwanwitsch Studies on the Wing pattern of *Catagramma* and Related Genera of South American Nymphalid Butterflies.—Dr R. Broom Note on the Milk Dentition of *Australopithecus*.—J W Low Contributions to the Development of the Pelvic Girdle III The Pelvic Girdle and its Related Musculature in Monotremes.—J S. Dunkerly A Note on Parasites and the Natural Selection Theory—S Hirst Additional Notes on Australian Mites of the Family Trombidiidæ with Descriptions of New Forms

INSTITUTION OF CIVIL ENGINEERS, at 6.—C Gribble Impact in Railway Bridges with Particular Reference to the Report of the Bridge Stress Committee

LONDON NATURAL HISTORY SOCIETY (at Winchester House), at 6 30—W H Spreadbury Common Birds of London a Country

INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre) (at Engineers Club Manchester), at 7—E B Wedmore Dr W B Whitney, and C E R Bruce An Introduction to Researches on Circuit Breaking

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), at 7—W I Shand Pictorial Impressions in Italy

INSTITUTION OF AUTOMOBILE ENGINEERS (Graduates Meeting) (at Broad gate Cafe, Coventry), at 7 15—W S. Ascough Pistons

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Middlesbrough Branch) (at Cleveland Scientific and Technical Institution, Middlesbrough) at 7 30

INSTITUTION OF AUTOMOBILE ENGINEERS (at Royal Society of Arts), at 7 45—A E L Chorlton The Heavy Oil Engine on Road and Rail

ROYAL SOCIETY OF MEDICINE (Pathology Section) (Laboratory Meeting in Pathological Department, St Thomas's Hospital Medical School) at 8—J Bamforth Two Cases of Purpura with Unusual Blood Pictures for which Splenectomy was Performed—R. J V Pulvertaft Experiments with Streptococcal Toxin and Hæmolysins.—J O Oliver Group Complement Fixation with the Gram Negative Cocci

ROYAL SOCIETY OF MEDICINE (Orthopædics Section), at 8 30—Dr M Smith Petersen Sir Robert Jones and others Discussion on The Diagnosis and Treatment of Low Back Pain

TELEVISION SOCIETY—Annual General Meeting

WEDNESDAY MARCH 6

ROYAL SOCIETY OF MEDICINE (History of Medicine Section) at 5—Dr R. Campbell Thompson Assyrian Remedies for Diseases of the Ears

GEOLOGICAL SOCIETY OF LONDON at 5 30—Dr M M Ogilvie Gordon The Structure of the Western Dolomites (Lecture)

NEWCOMEN SOCIETY FOR THE STUDY OF THE HISTORY OF ENGINEERING AND TECHNOLOGY (in Demonstration Room Science Museum) at 5 30—H O Clark A Comparison between French and English Windmills

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section) at 6—Capt. P P Eckersley and A B Howe Single Wave length Working

WOMEN'S ENGINEERING SOCIETY (at 41 Cadogan Square), at 8—Lady Bailey Flight round Africa.

UNIVERSITY OF GLASGOW ALCHEMISTS CLUB (at Glasgow University) at 7—Annual General Meeting

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (at Caxton Hall), at 7—Dr B J Owen The Desiccation of Vegetable Material

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (Annual General Meeting) (at Chemical Society) at 8—A. L. Andrew The Cryoscopic Method for the Detection of Added Water in Milk—Christina Mary Fear The Alkaloid Test for Tannin

ROYAL SOCIETY OF ARTS, at 8—T Purvis Commercial Art its Value in Business and Art

ENTOMOLOGICAL SOCIETY OF LONDON at 8

THURSDAY, MARCH 7

ROYAL SOCIETY at 4 30—Prof T M Lowry and A G Nasini The Molecular Dimensions of Organic Compounds Part I General Considerations—A G Nasini The Molecular Dimensions of Organic Compounds Parts II and III—Prof W A Bone and R P Frazer A Photographic Investigation of Flame Movements in Carbonic Oxide Oxygen Explosions—H S Patterson Prof R Whytlaw Gray and W Cawood Some Observations on the Condensation of Water on Smoke Particles The Process of Coagulation in Smokes, The Electrified Particles in Smokes The Structure of Complex Smoke Particles—*Papers to be read in title only*—J G Semple Cremona Transformations of Space of Four Dimensions by Means of Quadrics and the Reverse Transformations—T L. Ibbs and A. A Hirst The Thermal Conductivity of Gas Mixtures.—D M Newitt B J Byrne and H W Strong Equilibrium in the System Methyl Alcohol-Hydrogen-Carbonic Oxide—Prof W A Bone F R Weston and D A Winter Further Experiments on the Combustion of Well-dried Carbon Monoxide and Oxygen Mixtures Part III—Dr E K Rideal and O H Wansbrough-Jones An Investigation on the Combustion of Platinum—R. W Ditchburn and F L. Arnot The Ionisation of Potassium Vapour—Prof O W Richardson and P M Davidson The Spectrum of H_2 the Bands Analogous to the Parhelium Line Spectrum—R C Johnson and R. K Asundi A New Band System of Carbon Monoxide—Prof H. A Wilson The Theory of Cracking Petroleum—Prof T H Havelock The Dispersion of Double Refraction in Quartz—Prof A Fowler The Arc Spectrum of Silicon

ROYAL COLLEGE OF PHYSICIANS OF LONDON at 5—Prof E B Verney Polyuria (Goulstonian Lectures) (I)

ROYAL INSTITUTION OF GREAT BRITAIN at 5 15.—Rev W H Draper The Use of Language and its Difficulties

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6 30.—C N H Lock Airscrew Body Interference

SOCIETY OF CHEMICAL INDUSTRY (Bristol Section) (Annual Meeting) (at Bristol University), at 7 30—Chairman's Address

INSTITUTE OF METALS (London Local Section) (at 83 Pall Mall), at 7 30.—W T Griffiths 'Theory, 'Practice, and Nickel

INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre—Dublin) (at Trinity College, Dublin), at 7 45—E S. Ritter Picture Telegraphy (Lecture)

CHEMICAL SOCIETY, at 8.—F G Mann The Stability of Complex Metallic Salts.—A B Manning The Determination of Unsaturated and Aromatic Hydrocarbons in Light Oils and Motor Spirits—S. Glasstone Studies of Electrolytic Polarisation Part VII Complex Cyanides. (*a*) Silver Part VIII Complex Cyanides. (*b*) Copper

INSTITUTE OF CHEMISTRY (Manchester and District Section) (at Manchester)—Annual General Meeting

FRIDAY, MARCH 8

ANDERSONIAN CHEMICAL SOCIETY (at Royal Technical College, Glasgow) at 8 15—W H Nuttall Rubber and its Commercial Applications.

ROYAL SOCIETY OF ARTS (Indian Meeting), at 4.30—W H Moreland The Indian Peasant in History

ROYAL ASTRONOMICAL SOCIETY at 5—Prof S. Chapman Solar Streams of Corpuscles their Geometry Absorption of Light and Penetration—N Goryatscheff Occultations of Stars by the Moon observed at the Tomsk University Observatory during the Year 1928.—Prof S. Chapman and V C A Ferraro The Electrical State of Solar Streams.—Y Ohman Astronomical Consequences of the Polarisation of Fluorescence—W H. McCrea The Hydrogen Chromosphere—C L. Janssen Provisional Elements of the Binary System β G C 12807

IMPERIAL COLLEGE CHEMICAL SOCIETY (in Main Chemistry Lecture Theatre, Royal College of Science) at 5—Dr N V Sidgwick Chemical Linkage

PHYSICAL SOCIETY (at Imperial College of Science), at 5—Dr E Griffiths and J H Awbery The Dependence of the Mobility of Ions in Air on the Relative Humidity—Prof A M Tyndall Some Unsolved Problems relating to the Mobility of Gaseous Ions—followed by a General Discussion on the Mobility of Ions

ROYAL SOCIETY OF MEDICINE (Clinical Section), at 5 30

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (Annual Meeting) (at Liverpool University), at 6—L. O Newton Boiler Feed Water

MALACOLOGICAL SOCIETY OF LONDON (in Zoological Department, University College) at 6

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN at 7—J A Hall Bromide Papers

JUNIOR INSTITUTION OF ENGINEERS at 7 30—S H Hole Road Transport (Chairman's Address)

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Jointly with Leicester Association of Engineers) (at Secular Hall Leicester), at 7 30—Dr J Newton Friend Science in Antiquity

INSTITUTE OF METALS (Sheffield Local Section) (at Sheffield University) at 7 30—D F Campbell and W S Gifford Progress in Electric Furnaces

OIL AND COLOUR CHEMISTS ASSOCIATION (Manchester Section) (at Milton Hall Manchester) at 7 30—S. T Kinsman The Fastness to Light of Lake Colours

ROYAL INSTITUTION OF GREAT BRITAIN at 9—Prof T F Tout The Place of Women in Later Medieval Civilisation

SATURDAY MARCH 9

ROYAL INSTITUTION OF GREAT BRITAIN at 3—Sir Ernest Rutherford Molecular Motions in Rarefied Gases (II).

PUBLIC LECTURES

FRIDAY, MARCH 1

UNIVERSITY COLLEGE, at 5—Dr F A Freeth The Four Component System in Peace and War

SATURDAY MARCH 2

HORNIMAN MUSEUM (Forest Hill) at 3 30—Prof J R Ainsworth Davis English Food Past and Present

MONDAY MARCH 4

KING'S COLLEGE OF HOUSEHOLD AND SOCIAL SCIENCE, at 4 45—Sir Alan Cobham Adventures in Empire Flight

LEEDS UNIVERSITY at 5 15—Prof D M S Watson Animal Flight.

Land and Industry

THE very heavy imports of foodstuffs into Great Britain and the urgent need for increasing the home production of food have been emphasised with wearisome iteration these many years past. A study of the trade returns for 1928 shows clearly enough that the position in this respect is getting worse. But our dependence on other countries to save us from starvation is only one part of the story. There are many other collateral factors of vital consequence. For example, it is not well that nine-tenths of our population should be entirely urban, completely exiled from the land, and wholly bereft of any land interest whatever. We may not all agree with what Mr. Galsworthy says about 'town blight,' but no one who has seriously thought about the matter, no one who has any appreciation of the teaching of history, can doubt that this entire exclusion from the land and all that it means is a potent source of national weakness, or at least of national one-sidedness.

Then, again, there is the vitally important question of leisure and its proper use. This has been hitherto a little neglected by economists, and yet, with the comparatively short hours of work now in vogue, it is a matter of the utmost moral and economic significance: the more so, in view of the increasing monotony of the greater part of the factory and office work of to-day, and mainly carried on indoors. These considerations point to the supreme need for a more natural and outdoor form of recreative work, such as would be provided by a land interest, as a powerful antidote to the present indoor monotony of work and the general artificiality of town life. The national love of outdoor sport, if sufficient facilities could be provided for its adequate expression and exercise, may be thought sufficient mitigation. But always there are more spectators than players, and we believe that there are many of both sexes and of all ages to whom some kind of land interest would make a more powerful appeal, and would certainly prove more useful and economically stronger. It is a pity that the allotment movement of the War period has not been more vigorously continued and extended since. It was a great deal better than nothing, though far from being the best thing of its kind that could be provided. The national housing programme offered the opportunity for something vastly better. That opportunity has been missed so far.

In fact, despite the very obvious and rather

disconcerting factors in our modern industrial civilisation noted above, very little has been done, at all events in Great Britain, where it is perhaps more urgently needed than in any other country, to counteract what must be described, without exaggeration, as a serious social evil We have had, it is true, much talk of 'back to the land,' really a fatuous and useless shibboleth in England, many acres of small holding legislation, for the most part derelict and only applicable to a small minority, and endless discussion of agricultural policies leading to little or nothing

We shall never be a nation of peasant proprietors despite the panegyrics of Mill, Sismondi, and others on that very admirable ideal, and therefore it might be advisable to look for something else, less drastic and complete, but more practicable, let us hope The suggestion has been made not infrequently in recent years that a partial return to the land would be the best, a part time recreative interest rather than a whole time occupation It would be merely a modified and improved form of industry cum agriculture which largely characterised our economic structure in pre industrial days, when the Lancashire weavers had their little farms and the Sheffield cutlers were noted for their culture of flowers To day it is a prominent feature in the United States of America, in Canada and other British dominions overseas, in many parts of Europe, and is struggling to make some headway in Great Britain, where, as already intimated, it is more urgently needed than anywhere It means the provision of homes or homesteads worth the name, with gardens and perhaps even orchards and greenhouses, embodying not only the primeval need of shelter but also the still more primeval need of food

So far from being original and novel, this idea goes back to Babylonian times Within the mighty walls of that ancient city were sheltered fields and gardens to provide food in time of siege, and indeed at all times Some day the same imperative need may be ours, and we should make provision in time A great deal has already been done along these lines in other countries, especially in the United States, and to some extent on the Continent It is strange indeed that the need for this sort of thing has been more clearly realised in the United States, where there is no preponderating town population and no 80 per cent dependence on foreign food, but it has been adopted over there not so much from the point of view of food supply but rather as a refreshing counter current to modern artificiality and rush It is a profitable hobby too, healthy, and absorbingly interesting In the case of the smaller holdings of industrial workers, from a quarter acre to one or more acres in extent, it is possible to pay the greater part of the rent—or, better still, the mortgage interest and sinking fund—from the garden and orchard produce, or, what comes to the same thing, save equivalent expenditure on vegetables and fruit for the home This would appear to be a very sound financial basis on which to establish any housing policy, and there, too, is the right solution of the leisure or 'dopo lavoro' problem as it is called in Italy

Italy has taken up the 'dopo lavoro' (after-work) or leisure question with enthusiasm in conjunction with home food supply It came up before the International Labour Conference at Geneva in 1924, but was discussed in Italian labour and commercial journals long before that date In Germany the great firm of Krupps some years ago purchased estates and farms for the production of food for its employees, many of whom became the proud owners of small holdings It is scarcely necessary to point out here that no shrewder blow could be struck at communism and general labour unrest than such a policy as this The ownership of a little bit of one's own country is surely the safest guarantee for sound and sober citizenship and real patriotism, and gives a man something to do other than listening to street corner oratory Several firms in Germany and Austria have followed the example of Krupps The municipality of Vienna has based its extensive housing schemes largely on this principle of ownership and land settlement It seems, indeed, to be the only common sense principle on which to base any housing programme, except blocks of flats or tenements to replace slums, and possibly even this exception is not often valid The subject presents many and varied openings and ramifications It has an important bearing on unemployment, emigration, and land settlement

So far, only one form of combining industry and agriculture, farm and factory, has been considered There is not space to deal with the converse form, that of giving the agricultural worker an industrial or rather a manufacturing interest, in the form of village and cottage industries and handicrafts This is another chapter, and is a well known economic feature in India, also in Switzerland, Norway, and elsewhere It is being taken up in Canada, for example, in Quebec, where the need for some occupation in bad weather and during the dark days of winter is very evident In these and other ways a people may be made to work harder

without knowing it, or, knowing it, they enjoy it It is doubtful if, in the sterner, strenuous, and fiercely competitive days ahead—if they have not already arrived—we can much longer afford to neglect this vital matter of using even our leisure to the best purpose At least greater opportunity for such could be afforded, and is within the range of practical politics

The question of leisure occupation for those already in work, important as it is, almost fades into insignificance, however, beside the greater question of unemployment So far as the programmes of the chief political parties have been revealed in view of the coming election, there does not appear to be anything refreshingly original or practically effective in contemplation to deal with this great evil, and it is not, of course, pretended in this article that the suggestions herein tentatively offered contain anything very helpful by way of remedy or mitigation It is, however, firmly believed that a vast field of employment could be opened up along the lines of land settlement, land reclamation, village industries, combined with industrial enterprise, possibly a programme somewhat similar to that adopted for the Greek refugees

It is not possible here to go fully into this part of the subject, except to say that the land interest—allotment, small holding, or the like—could be more effectively provided in garden cities, industrial villages, and so forth, where new industries could be established, than in or near existing industrial centres where little or no land is available In any event, the new derating concessions should be a great help in establishing industrial small holdings, and the extent to which such holdings are already used by those engaged in other occupations is revealed by a recent study of small holding economics in one county alone, for example, Carmarthen Nearly fifty per cent of all holdings under fifty acres are occupied by persons with non agricultural employments, representing nearly every trade and profession, miners, general labourers, carpenters, butchers, and grocers being the chief We are glad to know in this connexion that in some districts in South Wales, where allotments have gone out of cultivation on account of inability to pay rent for them, or purchase seeds or manures, the Society of Friends is successfully reviving allotment holdings and providing facilities for unemployed miners to work them for the production of food There could be no better use for grants from the Central Coalfields Distress Fund, in suitable districts, than to encourage work on the land in this way

Reform of the British Patent System

IT is clear from statements which have been made in the House of Commons during the past few months that a serious state of affairs exists at the Patent Office On July 18, 1928, Mr Herbert Williams stated, in answer to a question, that 6300 complete specifications were awaiting first action by the examiner and that these arrears were accumulating at the rate of 67 per week On Feb 26 last, in answer to a further question, he stated that the arrears now amounted to 8400 complete specifications and were increasing at the rate of 76 per week Since about 20,000 complete specifications are filed annually, the work is therefore just over five months in arrear on the average

Figures given by Mr Williams in July indicate that while the number of specifications to be dealt with annually had increased by 26 per cent as compared with 1912, the strength of the examining staff had decreased by 10 per cent This economy, at a time when the Patent Office obtains a large and increasing surplus of fees over expenditure, appears to be most unjustifiable The present critical state of affairs could have been foreseen and provided against some years ago, for the input of patent applications has been steadily increasing since patent business became normal after the War The public has a right to know why such steps were not taken in good time Did the Comptroller of the Patent Office fail to warn the Minister or did the Minister fail to heed his warnings ? Or is it that, as in the case of certain other technical departments, there is interposed between the Minister and the technical chief a body of administrative officials who fail to appreciate technical requirements ?

Last October an important report on the reforms which are needed in the British patent system was published by the British Science Guild This report met with an enthusiastic reception from the financial, technical, and daily press, and we understand that it has received the formal support of a number of important bodies Asked whether the Board of Trade proposed to take any action in this connexion, Mr Herbert Williams stated on Feb 26 that the President of the Board proposed to set up a committee in due course to review existing patent law and practice

While the British Science Guild Committee may be congratulated on this promise of a result arising from its labours, some disappointment will be felt at the absence of any indication that the matter will be carried through expeditiously

Soft X-Rays from Crystal Faces

THESE experiments originated in an attempt to improve and extend those of Richardson and Chalklin on the generation of soft X rays from surfaces of tungsten formed by deposition *in vacuo* on carbon (*Proc Roy Soc*, A, **119**, p 71, 1928) In that investigation difficulties were met with owing to the deposition of impurities on the carbon target by the bombarding process necessary to secure the requisite high vacuum To avoid this difficulty we made a target like two doors folded together on a hinge We could bombard this target with the doors shut, and then open it out and so make the X ray tests on the inner surface which had been heated but not exposed to the residual gases in the tube

The tests are made by measuring the photoelectric current generated by the soft X rays when they fall on a nickel plate, dividing this by the primary thermionic current, plotting the fraction so obtained against the exciting voltage and looking for discontinuous changes of slope in the resulting curves On making this experiment we were surprised to find a large number of discontinuities extending all over the range from 20 to 560 volts These discontinuities are mostly well defined and quite persistent, and they repeated with a second target made from a specimen of spectroscopically pure arc carbon kindly supplied to us by Dr R C Johnson In this case the carbon was so soft that the hinge could not be made, and the surface of the target was protected during bombardment by a sliding shutter made from the same carbon

In the hope of simplifying the problem, we decided to try experiments in which the X rays were generated by bombarding a single crystal face of crystalline carbon Through the kindness of Prof W T Gordon we were able to obtain a diamond with a large natural face and some large pieces of natural crystalline graphite Unfortunately, the diamond was found to be unsuitable for the experiment, as an attempt to determine its electrical resistance showed it to be immeasurably high This would suggest that little confidence can be placed in the results of Lukirsky (*Zeits fur Physik*, **22** p 351, 1924) which were made with this substance A repetition of his experiments with the substitution of graphite carbon for diamond in this laboratory by Miss L P Davies led only to data which were very difficult to interpret, and, furthermore his results are incapable of reconciliation with the very reliable conclusions of Rudberg (*Proc Roy Soc*, A, **120**, p 385 1928)

After some trials we were able to split off a piece of graphite with a surface large enough to be suitable for testing The surface used was that at which natural graphite cleaves most easily (the 0001 plane) On testing the graphite surface between about 70 and 320 volts seventeen discontinuities have been found, each of which either agrees with a value or with the mean of two values a few volts apart, found previously with carbon Fifteen discontinuities which were present in this range with the carbon target are absent with the graphite target It should be added that the surface used was by no means perfect, so that it is possible that a still further reduction in the number of discontinuities might be effected if a more perfect surface could be obtained From these experiments there seems no doubt that the number of discontinuities from a single crystal surface is smaller than from a polycrystalline surface It is satisfactory to note that the *K* level discontinuity is not one of those which disappears

We should be grateful to any readers of NATURE who could supply us with any specimens of conducting crystals suitable for these experiments The materials must be capable of withstanding a bright red heat *in vacuo*

Soft X-Rays from a Single Nickel Crystal

AT the suggestion of Prof O W Richardson, an investigation was made on the excitation of soft X rays from a single crystal of nickel, kindly lent by Dr H H Potter, of the University of Bristol The face chosen was the [100] face and the range of potential was from 0 to 300 volts The experiment was conducted with an all quartz tube similar to the one used by Richardson and Chalklin (*Proc Roy Soc*, A, **110**, p 247, 1926) Curves were drawn between the applied potential and the energy of the soft X ray excited as measured by the usual photoelectric method When the bombarding current was maintained at about 1 5 milliamperes definite and strong inflections appeared at 63 8 72 2, 106 2, and 116 0 volts A very weak inflection was also noted at 94 4 volts No other inflections were obtained If, however, the thermionic current was increased to about 3 milliamperes, there appeared also, besides the four strong ones noted above, weak inflections at 129 0, 144 8 155 9, 179 9, 186 0, and 217 7 volts (all of which appear in the results of Thomas for nickel), while the inflection at 94 4 volts became stronger

As could be seen from the published microphotograph of the surface of a nickel crystal by Davisson and Germer (*Phy Rev*, II **30**, p 710, 1927), it is very difficult to obtain an ideally crystalline surface over an area of as much as 12 mm × 6 mm (the area used in these experiments), and there are bound to be some irregularities on the surface It looks, therefore, very probable that when an ideal crystal surface is used only four inflections appear, these being at 63 8, 72 2 106 2, and 116 0 volts The first two can be associated with transitions from the $M_{II\ III}$ level in the nickel atom, 63 8 volts representing the energy necessary to shift an electron from that level to the periphery of the atom and 72 2 representing the energy necessary to remove the electron altogether from the atom The emission data of Thoraeus (*Phil Mag*, vii **2** 2, p 1007, 1926) gives for the $M_{II\ III}$ level the value of 73 2 volts In the same manner the values 106 2 and 116 0 volts may be associated with similar transitions from the M_I level, the energy of which is 112 4 volts according to the same authority

It is well known that when a metal target (non crystalline) is heated strongly by electronic bombardment, the surface looks altered, probably because of the formation of small metallic crystals These crystals may in some manner be the origin of the large number of inflections observed by recent investigators Further, it would be interesting to determine the effect of a crystal surface on the secondary emission of electrons, since Prof Richardson has shown that there is a close similarity between the excitation of soft X rays and the emission of secondary electrons (*Proc Roy Soc*, A, **119**, p 531, 1928) Farnsworth (*Phy Rev*, II **31**, p 419, 1928) has

already reported that the characteristic secondary electron emission inflections from a crystal surface are different from those of ordinary metals between 0 and 40 volts It is proposed to repeat the soft X ray experiments with other crystals, as also to investigate the secondary electron emission from crystals further at higher potentials My sincere thanks are due to Prof Richardson for his kind help and encouragement, and to Dr H H Potter for the crystal of nickel

Incoherent Scattering

THERE are several surprising peculiarities of the phenomena of modification of wave length in scattering, but the most striking is the rareness with which one is able to find an infra red line to fit even approximately the frequency shifts observed On the other hand, there are many strong infra red lines which have no corresponding frequency shift Moreover there is scarcely any direct correlation of intensity even when there is a supposed match in frequency

The idea suggested by Smekal that a molecule may subtract from or add to an incident quantum one of its characteristic energy quanta and scatter the resultant sum or difference in a single quantum is so neat and clear that it is accepted as the explanation of the scattering experiments of Raman and Krishnan and others The most important characteristics of such a process are those just indicated which are not realised in the experiments

Kramer's and Heisenberg's correspondence principle treatment is much more successful in accounting for the facts, and Schrödinger's wave mechanics gives an almost identical result, formally, which is on closer inspection in even better accord with experiment The wave theory for the scattering of light of frequency ν by a system excited in two of its characteristic states—let us call them k and l—leads to terms incoherent with the incident radiation of frequencies $\nu_{kl} \pm \nu$ and with intensities proportional to the square of the quantities

$$A_{kn}A_{ln}\left[\frac{1}{\nu_{kn} \pm \nu} + \frac{1}{\nu_{ln} \mp \nu}\right](\nu_{kl} \pm \nu)^2$$

The upper signs or the lower signs are used throughout The A_{kn}, for example, is the matrix element $\int r\psi_k\psi_n dx$, which describes the intensity of the transition between states k and n, giving out radiation of

frequency $\nu_{kn} = \nu_k - \nu_n = \dfrac{E_k - E_n}{h}$

We see that the modified frequencies $\nu_{kl} \pm \nu$ differ from the incident ν, not by absorption frequencies (although these may also appear) but by differences between these That is to say, only when two allowed transitions (*i e* A_{kn} and A_{ln} different from zero) have a common level (n) is there any intensity in the scattered frequencies $\nu_{kl} \pm \nu = \pm(\nu_{kn} - \nu_{ln}) \pm \nu$

Examination of the data shows that the frequency shifts in scattered light can be interpreted in this way The case of carbon tetrachloride is not the most striking, but it is perhaps the simplest which has so far been tried Only two out of five frequency shifts coincide with known infra red lines These two correspond perhaps to the weakest shifted lines, while the infra red lines are the strongest The intensity formula indicates that the strongest frequency shifts should correspond to the frequency differences between the strongest fundamentals and the other fundamentals which end on the same level This rule suggested the energy diagram (Fig 1) It is believed to contain elements of reality, but should not be considered as a final and complete picture The numbers along the full vertical lines are wave numbers of the infra red lines due to transition indicated The numbers by the dotted lines are the differences between levels joined, and indicate frequency shifts to be expected in scattered light The one of 27 wave numbers would be too close to the exciting line to be observed The others were obtained from grating and prism plates, and are probably correct to a couple of wave numbers

The test of the theory is to compare the wave lengths calculated from this diagram with those observed The infra red data are from J Lecomte, "Le Spectre infrarouge," p 213, and the references there given The table gives the wave lengths which are directly connected with the frequency shifts All the other known lines are faint, and with one exception

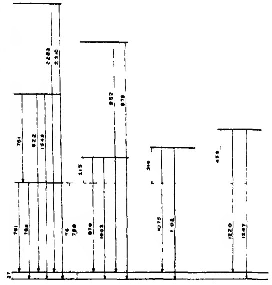

FIG 1

of much shorter and more uncertain wave length The exception is the weak line observed by Marvin at 15 μ Its interpretation is not yet definite The others are explicable as overtones or combinations of the levels shown In fact, just those combinations appear which, according to the wave theory, indicate the possibility of the modified lines actually observed

TABLE

Calc (μ)	13 14	12 69	10·24	9 97	9 10	9 07	8 20	8 0.	6 57	6 46
Obs (μ)	13 10	12 72	10 23	9 96	9 3	9 07	8 26	8 02	6 57	6 45

The agreement is in every case well within the experimental latitude The significance and power of the scattering experiments in unravelling infra red spectra is very much greater than if they merely checked infra red measurements With their help and with more precise infra red data it may be hoped that the vibrations of complex molecules will be interpreted A beginning will be made in a fuller account of this work

Luminous Discharge in Gases at Low Pressure

Considering the very minute quantities of matter required for a luminous discharge in gases at low pressures excited by electric oscillations of high frequency, this method would seem to be specially adapted for spectroscopic tests for the products from atomic disintegration spontaneous as well as artificial. Experiments to this end were started some time ago in the Institut fur Radiumforschung of Vienna and have recently been carried further in this Institute. The following phenomena, which appear to be of general interest, were observed.

In order to make the discharge pass through narrower tubes and in gases of still lower pressure than what appears to have been feasible in the experiments of Kirchner, Gill and Donaldson, and others, oscillations of still higher frequency, 10^8 cycles per second, were applied to electrodeless discharge tubes made from transparent silica. Oscillations of this frequency and of considerabble energy, 45 watts or more, can now easily be realised by means of commercial short wave transmission valves. A luminous discharge was found to pass through tubes only 5 mm wide, and it could be maintained even at the lowest pressure realised by means of a powerful molecular pump backed by an oil pump of the Zenco type. The pressure was then much too low to be measured on the Gaede high vacuum gauge, reading to 10^{-5} mm of mercury and communicating with the discharge tube through a mercury trap cooled with liquid air.

At the lowest pressure the luminosity from the gas itself within the discharge tube was very faint and bluish in colour, whereas the silica showed a strong fluorescence in blue or in blue green. A few silica tubes gave a brilliant fluorescence in red which does not seem to have been observed before. Thermo luminescence and after glow of the silica were also manifest. An ultra violet component of the latter may be assumed to give the initial ionisation required for starting the discharge after a brief interruption of the electric oscillations. Restarting the oscillations after a longer pause, the tube, when highly exhausted, generally fails to light up until ultra violet light from, say, a cadmium spark, is allowed to fall on it.

On passing the discharge through the exhausted tube when disconnected from the pump, a curious phenomenon was observed. The luminosity rapidly increases, and from a faint blue glow takes on a white hue of increasing brightness, the manometer at the same time showing a considerable rise in pressure. Adsorbed gases cannot be held responsible for the effect, which remains unabated when the pump has been running for several hours, and is also unaffected by baking out the discharge tube for more than an hour at 600° C in an electric furnace. The production of gas goes on at a rate of about 1 c mm N T P per minute at very low pressure, and is noticeable even after the pressure has increased to several hundredths of a millimetre of mercury.

The only possible explanation of this phenomenon seems to be that silica is decomposed, releasing oxygen, under the action of the electric oscillations, or rather by ultra violet light of very short wave length generated at the discharge. Whether the active rays are the strong emission lines of oxygen itself in the far Lyman region will have to be settled by means of a vacuum spectrograph. Light transmissible through silica seems to be ineffective, since no sensible rise of pressure was noticed when the exhausted discharge tube with the oscillations off was exposed for more than one hour to the intense light from a quartz mercury lamp close to it.

The above explanation is in agreement with the results from recent observations by Gillam and Morton (*Phil Mag*, p 1123, December 1928), who found the general decrease with age in the emission from quartz mercury lamps to be due to a deposit of silicon over the inside of the walls, caused by decomposition of the silica. Anyhow, my experiments prove that the presence of mercury vapour is not essential for the effect. Also, judging from the relative magnitude of the effect in both cases, one would infer that the light from the oscillating discharge is much richer in active components than the mercury light.

The light emitted from the self-generated gas was examined in the visible region by spectroscope and spectrograph, and also, in the ultra violet, by a medium sized quartz spectrograph, the plates showing that its spectrum is rich in strong bands, especially in the ultra violet. Oxygen, from permanganate of potassium, when introduced into the discharge tube, gave a different light of yellow colour with a different and much fainter band spectrum which, however, very soon merged into that of the self generated gas and took on its white colour. The explanation was found by applying a tuft of cotton wool soaked in liquid air to the tip of the discharge tube, when the white light disappeared and was replaced by the yellow oxygen light, the manometer showing a progressive fall of pressure. On removing the liquid air the beautiful snow white light reappeared and the pressure rose, but only by about two thirds of the previous reduction. This proves that the oxygen, under the action of the oscillations, is more or less completely transformed into ozone, which gas is condensed at − 190°, the vapour pressure being at that temperature only a few thousandths of a millimetre of mercury. The spectrum from the white light of the self generated gas, which is identical with that from the ozonised oxygen, must therefore represent the band spectrum of ozone with a few sharp lines from elementary oxygen superimposed. By means of a larger quartz spectrograph this band spectrum has now been resolved into characteristic groups of lines, which are at present being examined. The fluorescent and chemical effects of the 'active' radiation assumed to exist within the discharge tube will be further studied.

This method of excitation seems to be particularly adapted for the study of band spectra, whereas for the purpose mentioned at the beginning of this letter, the steady production of oxygen within the discharge tube remains a serious complication. Possibly this effect may be a contributory cause of the softening of deep-therapy Röntgen tubes and of transmission valves.

Solutions and Heat Engines

In Dr Holmyard's informed and charming review, under the title "The Theory of Atoms," in Nature of Feb 16, the statement is made that Hellas bequeathed to civilisation the priceless gift of logical deduction but lacked the spirit of modern science. "Everything," said Thales, "is full of gods."

The motive power of modern experimental science, without doubt, is a certain spirit but so highly diluted that it is not easily discerned: the atmosphere is so befogged with gods. The jesuitical notice, following Dr Holmyard's, by an anonymous reviewer of Dr Haldane's book on "Gases and Liquids," is an exemplification of this thesis. A certain school has long elected to worship van't Hoff—nothing that is said will lead its members to examine the premises of their deity's osmotic doctrine (hypothesis). Being

disputed, it cannot be called a theory The reviewer altogether disregards Dr Haldane's contention that the solvent has been neglected and only the solute considered Van't Hoff never thought in terms of water his was a purely thermodynamic mind The hypothesis *is* inherently unintelligible The late Prof FitzGerald said so long ago There is no proof of bombardment by the solute molecules, the tendency is more and more to admit that the solute molecules, whatever their form, are anchored to the solvent scarcely a preparation for ballistic exercise Whence does the bombardment come in the Perrin experiment, in which only water and very minute resinous particles are in interaction ?

Worship is part of our nature a faith once imposed is all but fixed we scarcely ever ask ourselves whether the gods held up to us be false or not Hellas may have bequeathed to us the gift of logical deduction—it in no way follows that we have learnt to use the gift However much of so called science there may be in us, it is rarely in us to be scientific The main difficulty in dealing with problems of solutions comes from the tendency to take mathematical expressions too seriously and absolutely and greatly to overrate their value to treat them as if they had a sacred meaning rather than as devices for wrapping up and obscuring meaning We need to get rid of gods and to put more of the holy ghost into our musings, so that they be made with method I agree with Dr Haldane that in this matter of osmotic pressure we have but "engaged in idolatrous worship of un understood equations" In any case, the discussion of such problems should be open, not anonymous anonymous attack should not be permissible in our society HENRY E ARMSTRONG

MAY I inquire from Prof Armstrong whether it is jesuitical to ask Dr Haldane to consider what the effect of the bombardment of the solute molecules will be even if I hope that his answer may, after all, be favourable to van't Hoff ? Moreover, as Prof Armstrong wishes to enter the arena, may I ask him also to consider the same question ? That there is bombardment is not a subject for question unless we are prepared to give up the dynamical theory of matter Prof Armstrong asks, somewhat sceptically, whence the bombardment comes in the Perrin experiment Surely what Perrin achieved was to show *visibly* that the dynamical theory is true The particles *are* in rapid motion, and are frequently colliding and each collision produces its expected dynamical effect That there is bombardment is not merely a happy hypothesis, it is an observed fact It cannot be explained away by the assertion that it is 'unintelligible'

Prof Armstrong, however, in spite of the evidence of his senses—for I presume he has seen Brownian motion, though perhaps he has not himself experimented with it quantitatively—wishes to ignore its effect, and suggests instead that the solute molecules are anchored to the solvent I challenge him to show how a pressure can arise from such attachments He must bear in mind that when there is equilibrium between the liquids on the two sides of an osmotic membrane, the solution is at a higher *external* pressure (that is the fact which is directly observed), and that attractions between molecules always act to reduce the *external* pressure

Physical chemists do not ignore the solvent It assists in certain cases to break up the solute molecules, and especially in strong solutions it has a great modifying influence, so that a simple 'gas' calculation is quite insufficient We need not be surprised at this, because similar modifications are produced in gases at high pressure

Prof Armstrong holds strong beliefs on these questions I urge him to put them into logical form so that others may be led into the right path Those of us who have read his papers find no rational theory there from which osmotic pressure can be calculated He must remember, however, that forces do not arise out of nothing like gods of ancient mythology Let him not be afraid of an equation which, after all, is only a somewhat condensed form in which the quantitative results of our thinking can be expressed It, of course, need not be 'idolatrously worshipped', and indeed, it may be dispensed with, though the alternative methods of description are not so compendious Above all, let him learn that assertion, even when strong is no adequate substitute for proof

Again I ask Prof Armstrong to join Dr Haldane and consider the question as to what the effect of the known bombardment of the solute molecules will be when a semi permeable membrane is provided through which the solvent can flow if it is induced to do so THE REVIEWER

Diffuse Bands and Predissociation of Iodine Monochloride

THE absorption spectrum of iodine monochloride consists of a group of bands (group Cl*) with an upper convergence limit at about 17430 cm $^{-1}$ corresponding to the dissociation of ICl into a normal iodine atom and a chlorine atom in the 2^2P_1 state There is also another group (group I*) of which only two members (17446 cm $^{-1}$ and 17570 cm $^{-1}$) were observed by Gibson and Ramsperger Several further members of this group have since been observed (Gibson unpublished measurements) These are visible in the region between the convergence and the absorption maximum of the continuum of group Cl*

We have strong evidence that the convergence limit of group I* corresponds to dissociation of iodine monochloride into normal chlorine and excited iodine atoms A second continuum farther in the ultra violet has also been observed and probably corresponds to this same process The band 17446 cm $^{-1}$ of group I* shows the fine structure clearly The rotation lines are sharp near the head, but show a marked increase in width for large rotational quantum numbers The next following bands of this group are diffuse and fade out in the region of continuous absorption of group Cl* It seems very likely that this effect is of the same nature as that discovered by Henri and termed predissociation The place at which the widening of the rotation lines begins in the band 17446 cm $^{-1}$ corresponds within experimental error to the convergence limit of group Cl* This suggests strongly that interaction between the Cl* continuum and the discrete states of group I* is responsible for the diffuseness

A similar assumption has been made by Wentzel to account for the diffuseness of the lines corresponding to the higher terms of the p' series of Ca, and by Bonhoffer and Farkas and by Kronig to account for diffuse band spectra Kronig has shown that under favourable conditions the life period of a discrete state may be so shortened by the presence of a continuum that it becomes less than the period of rotation, in which case diffuseness may be expected Calculations were made by us using perturbations of the type considered by Kronig, which arise from the terms in the wave equation neglected in the separation of electronic and nuclear co ordinates (see *Z Physik*, 50, 347, 1928) A formula has been obtained (to be published shortly by Rice) which permits a direct quantitative calculation of the width of the rotation lines when the perturbation matrices are known

Kronig arrives at two results for the perturbations according as the quantum number n which determines the angular momentum of the electrons about the nuclear axis changes by ± 1 or remains constant in the radiationless transition. In the first case the width of the rotation line varies with the square of the quantum number j, which determines the total angular momentum. In the second case the width of the line is independent of j. Kronig has made rough estimates of the orders of magnitude of the perturbations. Using his estimates we cannot account for the observed width of the lines of higher rotational quantum number unless we take the first case in which n changes by ± 1 and the width is therefore proportional to j^2. We have reason to believe, however, that n has the same value for group Cl* as for group I*.

It is possible, however, to account for the magnitude of the effect, even in this case, if we take into account the fact that the eigenfunctions are oscillating functions of the co-ordinates. We have made calculations, using Kronig's estimate for the electronic eigenfunctions and making very reasonable assumptions as to the nature of the vibrational eigenfunctions of the two states. The vibrational eigenfunctions are approximately sine curves. It is entirely consistent with what we know of the energy and moment of inertia of the molecule in its two states to suppose that the eigenfunctions have nearly the same wave length and such a phase relationship as to produce a large effect. The calculations show that perturbations of the type considered by Kronig are then sufficient to account for the observed widths. The effect would be still further enhanced if the electronic eigenfunctions of the two states should coincide in a similar manner, in which case a less complete coincidence for the vibrational eigenfunctions would be sufficient to reproduce the experimental values.

Effect of Parathyroid Hormone on the Structure of Bone.

In the current issue of the *Journal of Experimental Medicine* (January 1929), Bauer, Aub, and Albright have reported that the administration of the parathyroid hormone (Parathormone, Eli Lilly), to rabbits over a period of 91 days in doses up to 8 units per diem results in a depletion of the trabeculæ of bone, without gross changes in the cortex. The X-ray plates showed that the bones contained less calcium than those of control animals belonging to the same litter, whilst the blood calcium increased to about 15 mgm. per cent as compared with a normal value of 10 mgm. per cent. In similar experiments with young rats the administration of parathormone did not give a similar result, but rather increased the number of trabeculæ and the density of the bones, whilst the blood calcium did not differ appreciably from that of untreated animals under similar conditions. With cats the results were entirely negative.

All these experiments were carried out with a diet rich in calcium.

It has for some time been recognised that the diseases osteitis fibrosa and osteomalacia are not infrequently associated with tumours or hyperplasias of the parathyroid glands. For example, parathyroid adenomata were found in the case of osteitis fibrosa described in great detail by Dawson and Struthers (1923) in a communication from this laboratory. In another case of the same disease also associated with parathyroid adenomata, more recently investigated from the biochemical point of view by one of us (C. G. L.), a very marked hypercalcæmia (17 mgm. per 100 c.c.) was found, together with a negative calcium balance (see Lambie, *Brit. Med. Jour.*, 1927). It appeared possible that in these cases the primary disturbance was the existence of the parathyroid tumour resulting in an excess production of the hormone over a long period. This would cause the hypercalcæmia, the negative calcium balance, and, presumably, the removal of calcium from the bones.

In order to test this hypothesis it was thought desirable to carry out experiments to ascertain what is in fact the effect of prolonged administration of parathyroid hormone upon the structure or bones. In preliminary experiments carried out with young growing rats, kept on an ordinary diet, in which two were used as controls and two were given 10 units each of parathormone per diem for 21 days, it was found on histological examination of the bones, that there was marked thinning of the trabeculæ in all the bones examined, especially the femora and vertebræ. In one of the two treated animals changes were also apparent in the cortex and in the epiphyseal cartilages. The bones, when dried, exhibited a greater tendency to fracture than did normal ones, and when ground up showed themselves to be more fibrous in texture. On chemical analysis it was found that the bones of the treated animals gave rise to less ash on ignition, but that the percentage of calcium in the whole bones was not significantly altered. It appears, therefore, that the inorganic ash from the treated animals actually contained more calcium than that of the untreated. This latter finding is puzzling, but may indicate a change in the form in which calcium exists in the bones of the treated animals.

These results confirm the positive findings of Bauer, Aub, and Albright as to the effect of parathyroid hormone upon the structure of bone, and it is hoped that by further experiments on these lines light may be thrown upon the pathogenesis of osteitis fibrosa, osteomalacia, and other bone dystrophies.

Spiral Markings on Carborundum Crystals.

In the course of another investigation, we have had occasion to examine crystals of carborundum under the microscope. These crystals were of very dark purplish colour with often a greenish sheen. Pure carborundum is said to show little colour, and the deep colour of the crystals of commerce is attributed to a minute quantity of free carbon, which doubtless tends to distort the lattice. Certain of our crystals exhibited, on their smooth hexagonal, basal pinakoid, surfaces, striations formed of numerous curved parallel lines, some thirty or forty microns apart, and roughly equidistant. Such striations have been mentioned in the literature. We were fortunate in finding a crystal face which showed that these markings may form a rather perfect spiral. A photomicrograph of this is reproduced as Fig. 1.

It will be seen that we are here in possession of a very clearly defined fact. Very often in science our theories are sufficiently clear, while the facts are much less so. The opposite is here true.

Three crystalline modifications of carborundum have been described, all of hexagonal symmetry, and striation by straight parallel lines occurs and calls for no comment. Spiral forms are very uncommon in inanimate Nature, but may perhaps occur when two types of crystal architecture alternate. That the observed spiral is related to the underlying hexagonal, or di-trigonal, structure may be seen from the slight flattening of the curvatures at azimuths 60° apart. Furthermore, the markings on different crystals have an obvious relation to the margins of the crystals when these are visible. It may be true that some carborundum crystals have a thin surface coating of silica, but hydrofluoric acid does not affect the markings we have observed.

FIG. 1

Not all specimens of carborundum exhibit such striation. This we have ourselves noted, while Negri, who states that he examined thousands of carborundum crystals with a hand lens and measured about one hundred on the goniometer, makes no mention of surface markings.

At its broadest portions the 'line' that forms the spiral can, interpreting merely in terms of appearances, be analysed into three lines: two marginal about six or seven microns apart (which may be the margins of a shallow channel or trough) and a third, between them, about two microns from the inside line. The outside line is in parts of its length fringed by outgoing excrescences, which may be of the same nature as the minute lozenge-shaped crystals which the photomicrograph shows lying in parallel orientations 60° apart.

Before venturing to put forward a too imaginative hypothesis, we should be glad to learn what others suggest in interpretation of this unusual phenomenon.

Polarisation of Compton Scattering according to Dirac's New Relativistic Dynamics.

IN a letter to NATURE of Dec. 1, 1928 (vol. 122, p. 843), I gave a formula for the intensity of the radiation scattered at right angles first by one and then by a second electron. In this formula, unfortunately, no account was taken of the change of frequency of the radiation during the first scattering. When this mistake, which has been kindly pointed out to me by Mr. Chr. Møller, is corrected, the formula in the letter referred to is replaced by

$$I = \frac{e^8}{2m^4c^8r^2r'^2}\frac{I_0}{(1+2\alpha)^3}\left\{\sin^2\theta + \frac{\alpha^2(2+4\alpha+3\alpha^2)}{2(1+\alpha)^2(1+2\alpha)}\right\}$$

Owing to this, the comparison of the theory with the measurements of Lukirsky comes out somewhat differently. Thus for $\theta = 0°$ the intensity is 5.3 per cent instead of 6.5 per cent of the intensity at 90°, when the wave-length is assumed to be 0.085 A., and agreement with Lukirsky's result would be obtained with a wave-length of 0.13 A. instead of 0.14 A.

The Language of Science.

IT has been said yet once again (NATURE, Feb. 2, p. 161) that 1 and 1 are not always 2. With great respect to Sir Oliver Lodge, I would suggest that there is here some confusion, if not of thought, at least of language. In the common use of our language when we say 1 and 1 make 2, we imply that each unit suffers no change in being added to, or rather associated with, the other. The usual, that is, not the special physical or chemical or biological, meaning of 1 and 1 is 1 + 1, where + stands for "associated with, but involving no change in either." Thus 1 (apple or mercury globule or amoeba) and 1 (apple or mercury globule or amoeba) *always* make 2 (apples or mercury globules or amoebæ). When, however, in the phrase 1 + 1, the symbol + is distinctly defined to mean (1) reacts physically with, or (2) reacts chemically with, or (3) reacts biologically with, the result, *as experience shows*, need not be 2. For example, 1 + 1 = 1 when + means (1) and the units are mercury globules; 1 + 1 = 4 when + means (3) and the units are amoebæ. In each of these cases a *change* has taken place, not a mental or an arithmetical addition.

To express any such change by saying simply 1 and 1 are 5 is to misuse our language. To go further, and say 1 and 1 are 2 and sometimes 5, is to confuse both thought and language.

Hamilton's Contributions to Geometrical Optics.

WE are at present engaged in preparing for the Royal Irish Academy the first volume of a collected edition of the mathematical papers of Sir William Rowan Hamilton. This volume is to contain Hamilton's contributions to geometrical optics.

If any readers of NATURE should happen to be in possession of any mathematical manuscripts written by Hamilton, we would be glad if they would communicate with one of us.

Erratum in Lodge's "Energy."

ON page 65 of numerous early copies of my little sixpenny book on "Energy," published by Messrs. Ernest Benn, Ltd., there is an erroneous reference to page 61, instead of to page 44. My object in making this reference was to call special attention to the apparently mysterious formula $ipq - iqp = h/2\pi$, which I anticipate will loom large in the physics of the future.

OLIVER LODGE.

Aspects of Fossil Botany

By Dr D H SCOTT, F R S

II EARLY FLORAS

DR CHURCH has reminded us that "the Beginnings of Botany are in the Sea" This is undoubtedly true, whether we accept his hypothesis of a universal ocean, or hold that the surface of the cooling earth was so corrugated that seas and continents co existed from the first The Plankton stage, of microscopic, free swimming organisms, postulated by Dr Church, has left no trace in the rocks We have, however, abundant evidence of the early presence of marine plants Apart from some disputable Cambrian records, we have numerous well preserved seaweeds from the Ordovician onwards It is, of course, mainly calcareous Algæ which have lent themselves to fossilisation The verticillate Siphoneæ, above all, form a fine evolutionary series, admirably investigated by Dr Julius Pia, of Vienna Their interest has perhaps scarcely been sufficiently recognised by botanists, though among geologists Prof Garwood has emphasised the importance of cal careous Algæ as rock builders The Siphoneæ, how ever, form a line of their own, without any relation to the land flora with which we are now concerned

At some unknown period the transmigration to dry land took place If we accept the theory of continents and oceans as equally ancient, it is quite probable that there may have been successive transmigrations As we shall see, highly organised land plants occur about contemporaneously with apparently primitive types Dr Bidder, in his address to Section D (Zoology) of the British Association in 1927, pointed out the probability of the early appearance of land organisms He regarded the occurrence of extensive beds of graphite in pre Cambrian rocks as evidence of an abundant vegetation in land locked waters, with every opportunity of migration on to the neigh bouring shores Thus a land vegetation may have made an early start, and some of the descendants may have persisted among later floras It is suggested that Hugh Miller's 'cone bearing tree' of the Middle Devonian may have been such a survival To quote Dr Bidder's words "There may be a class or classes of terrestrial animals or plants which have breathed air two or three times as long as those which left the sea in the Devonian"

We have, however, as yet no perfectly trust worthy record of land plants earlier than the Lower Devonian First of all there is the classical, but once disputed, *Psilophyton* of Dawson, with its rhizome, forked aerial stems, bearing thorns but no leaves, and large terminal sporangia There seems to be little doubt that Dawson's descrip tion was essentially correct The contemporary *Arthrostigma* was like a larger *Psilophyton*

The oldest known land plant with well preserved structure is *Gosslingia breconensis*, recently dis covered by Dr Heard in the Lower Devonian of South Wales In habit this was something like *Psilophyton*, the branches, as in that genus, had circinate tips It is a curious fact that circinate venation, often found in these early plants, is older than the frond itself, for it occurs on thalloid branches not yet differentiated as leaves *Gosslingia* had a well developed vascular cylinder, considerably larger than in the somewhat later Rhyniaceæ The wood was evidently developed centripetally, contrary, as it appears, to the direction in the family just mentioned Stomata were detected, as in the contemporary *Psilophyton*, in which Mr W N Edwards demonstrated them very clearly The great antiquity of the typical stoma is interesting but not surprising, for we know that this organ is common to Bryophytes and vascular plants *Gosslingia* also possessed terminal bodies which are interpreted as sporangia

It is unnecessary to recapitulate the characters of the Middle Old Red Sandstone Rhyniaceæ, now familiar to botanists A word may be said as to their relation to the Bryophytes, as indicated chiefly in the somewhat *Sphagnum* like sporogonium of *Hornea* and Halle's *Sporogonites* Dr Church has gone so far as to say that '*Rhynia* and *Hornea* between them present all the characters deduced as significant for early Bryophyta", and Prof Bower, with more caution, maintains that "the new facts are thus seen to link the Bryophytes and the Pteridophytes more closely together than ever before" We may accept this latter statement, and then the question arises whether these supposed Devonian intermediates were on the up grade or the down grade Were they on the way to become full blown Pteridophytes, or in course of reduction to a moss like level? Here we will only recall Haberlandt's opinion that the mosses were reduced forms At that time one asked But reduced from *what*? Possibly the Rhyniaceæ may suggest an answer

The late Dr Arber, at a time when only *Rhynia* was known, took a different view, for he thought that this genus represented "a now obsolete race of Thallophyta" He was so far justified that the Rhyniaceæ in their external morphology are no more complex than some purely thalloid seaweeds, such as *Polyides* or *Pycnophycus* It is an interest ing question whether any of the other early fossils suggest an algal connexion *Hicklingia* of Middle, and *Zosterophyllum* of Lower Old Red Sandstone age, both have a somewhat alga like habit, and yet were probably (certainly in the latter case) vascular plants *Pseudosporochnus* (Middle De vonian), the largest of all these plants, probably 10 ft high, with a bulbous base, thick stem and numerous fine branches, has all the appearance of a big seaweed, but this too was a vascular plant *Fœrstia furcata*, an Upper Devonian fossil, though fragmentary, combines algal structure with the spores and cuticle of a land plant As Kidston and Lang say, it "almost serves to break down any sharp distinction between Algæ and the

simplest Pteridophyta " *Milleria* (formerly *Psilophyton*), on the other hand, "appears to approach, without reaching, the more definitely fern like forms that come into evidence in the Upper Devonian " (Lang)

We may now leave these simpler types and pass on to definitely leafy plants, such as the genus *Asteroxylon* The Rhynie species, *A Mackiei*, is now well known It will be remembered that the connexion of the associated sporangia and sporangiophores with the plant has never been proved The German species, *A elberfeldense*, of perhaps somewhat later age, serves to remove any doubt, for the plant bore, towards the summit, naked branches, resembling the Rhynie sporangiophores, and in two cases sporangia were found upon them Kräusel and Weyland's species combined the external features of the form genera *Thursophyton*, *Psilophyton*, and *Hostimella* It differs in definite respects from *A Mackiei*, notably in the apparent presence of a pith in the stele of the main axis Thus *Asteroxylon* appears really to present the extraordinary combination of characters attributed to it by Kidston and Lang—the anatomy and vegetative habit of a Lycopod, with a reproductive apparatus suggesting that of some of the Carboniferous ferns Another early plant, looking like a Lycopod, is *Protolepidodendron*, only known by its external features

Among Kräusel and Weyland s discoveries at Elberfeld, in the Upper Middle Devonian, are the two oldest known Articulatæ, *Hyenia* and *Calamophyton* The most interesting point is the fructification, which in each case consists of a lax cone, bearing no bracts, but only sporangiophores, which are forked and support pendulous sporangia The absence of bracts in these ' Protoarticulatæ ' supports the view of Lady Isabel Browne that these sterile organs were a later intercalation in the Calamarian cone

The variety of Early Devonian plants was naturally far greater than the few better known types here mentioned would indicate For example, Prof Lang, in his assiduous investigation of the Old Red Sandstone flora of Scotland, found eight different kinds of spore in the fish beds of Cromarty They run up to 400μ in diameter, and some may thus have been megaspores One type has been identified by Kräusel and Weyland with the spores of the Elberfeld tree fern *Aneurophyton germanicum*

Aneurophyton was a tree fern in habit, but its affinities are quite uncertain All parts of the plant are known stem, root, fronds, and, to a certain extent, the fructification There was much secondary wood, resembling that of *Palæopitys Milleri* Quite recently the primary wood has been discovered It was solid and three lobed in transverse section, recalling that of the Lower Carboniferous genus *Stenomyelon* It is a remarkable fact that all parts of the frond show stem structure Only the ultimate leaflets are regarded as truly foliar, they have no vascular strand at all—hence the generic name The sporangia are borne in clusters on special leaflets The plant bears a general resemblance to *Eospermatopteris*, but there is no evidence of seeds *Palæopitys Milleri* (Middle Old Red of Cromarty), as just mentioned, has somewhat similar wood structure to that of *Aneurophyton*, but nothing is known of its habit The structure, while not that of a typical Gymnosperm, is more like a Gymnosperm than anything else, and to that extent may justify the discoverer's bold description of it (in 1847) as a "cone bearing tree" At any rate it is a highly organised plant to find at so low a horizon

Returning to the Elberfeld records, we must note the remarkable discovery of a Middle Devonian *Cladoxylon* (*C scoparium*), the oldest species known, and the only one in which the external habit and something of the fructification are shown The complex anatomy is exactly that of the well known species first described by Unger in 1856 The leaves are numerous, small, forked appendages, very different from the large fronds which, on anatomical evidence, appear to have characterised the Thuringian Cladoxylons It has been suggested by Dr Hirmer that the genus (following the analogy of *Asteroxylon*) possessed leaves of two categories, the small appendages of the Elberfeld species representing Lygnier s ' phylloids,' while the massive fronds of the later forms were true leaves derived from modified branch systems The sporangia of *C scoparium* were borne on the margins of lobed outgrowths, differing in shape from the vegetative foliage Nothing was found to support the hypothesis that *Cladoxylon* belonged to the Pteridosperms

We have, in fact, apart from *Eospermatopteris*, no direct evidence for the occurrence of seed plants in Devonian times The leaves of the genus *Psygmophyllum*, which goes back at least to the Middle Devonian, are somewhat like those of the Maidenhair tree, and appear to have belonged to woody plants One may imagine that we have in them an early race of Gymnosperms, but habit is notoriously deceptive A fossil found in the Middle Old Red Sandstone of both Orkney and Caithness, named *Hostimella racemosa* by Lang, bears lateral bodies which may be either sporangia or seeds, no spores could be obtained from them, but neither is there any evidence of seed nature

We now come to *Eospermatopteris*, the tree of the fossil forest of Gilboa in the State of New York A great flood on the Schoharie Creek exposed five stumps in 1869 They were referred to Sir William Dawson, who named them as two species, *Psaronius erianus* and *P textilis* It turned out to be true that the plants were really tree ferns in habit In recent years further exposures have revealed hundreds of stumps scattered over a district 1⅜ miles in length, and occurring at three different levels The stumps attain a diameter of 3 feet or more Portions of the stem and large compound fronds of the plants are associated with the rooted stumps Seeds were first detected by Dr Ruedemann in 1920 There are numerous specimens associated with fragments of the fronds They were investigated by Miss Goldring, who has published full and excellent descriptions, to her the name *Eospermatopteris* is due The seeds are

borne, often in pairs, on stalks, they are about 5 6 mm long by 3 mm broad, and are described as cupulate They appear to be perfectly clear seeds, so far as impressions can show Male organs, rather large terminal discs, with apparent impressions of sporangia on the lower surface, have also been observed This, then, is the oldest seed plant known, for the age is undoubtedly no later than Upper Devonian

We may now briefly review the results of our rapid survey Recent research has revealed, in the Early Devonian vascular plants far simpler in structure than any known before We can no longer regard these simpler types as reduced, for there are too many of them With these primitive forms, however, much more advanced types are associated, possibly, as Dr Bidder suggests, the survivors of an earlier land flora

Lignier's theory of the double origin of the leaf, from emergences forming 'phylloids,' on one hand, and from thallus branches forming true leaves, on the other, seems to find strong confirmation from the early flora, as, for example, in *Asteroxylon* In many cases the circinate tips of thalloid branches clearly indicate incipient fronds

On the whole, the data now available favour the rise of the land flora from a well developed thalloid stock of marine origin, which branched out into the two main Archegoniate lines, the mosses and the ferns

The Progress of Marine Propulsion

By Engineer Captain Edgar C Smith O B E R N

NEVER since Fulton launched the *Clermont* or Bell built the *Comet* has there at any time been a fixed or standard type of machinery for all ships Inventions improvements innovations have followed in rapid succession, and the history of marine engineering presents an endless and bewildering variety of engines and boilers which have been adopted one day, only to be superseded by better ones the next With all this change and development however designers have never before been faced with the problem of choosing between so many rival methods of driving ships as they have to day each method of propulsion making by its performance or promise some claim to consideration Modern marine engineering embraces in its scope not only steam boilers and steam engines, but also steam turbines oil engines of various types, and also the use of electricity on an extensive scale

One of the most notable steps in the progress of the marine engine was the adoption of compound working associated with the name of John Elder, another the introduction of the triple expansion engine by Alexander Kirk, another stage in marine propulsion was marked by the application of the Parsons steam turbine, while to day there is an ever-increasing fleet of ships driven by Diesel oil engines The advance made during the last sixty years will be realised by comparing the Cunard ships of 1860 with modern liners Then no Cunard ship used more than 30 lb pressure in her boilers the greatest horse power in any ship was 4200, found in the *Scotia*, while the coal consumption was 3 3½ lb per h p per hour To day, ships are running with 350 400 lb pressure, the total horse power of a big Atlantic liner is 70 000 80 000, while in the most modern steam machinery less than ¾ lb of oil per h p per hour is used At one time, Great Britain built 80 per cent of the steamships of the world Owing to various causes, one of which is the rise of great shipbuilding yards abroad, this proportion has fallen considerably, yet the volume of construction and marine engineering remains very large, and there is no slackening of the effort to maintain our position For a long period marine engineering was largely a matter of experience and rule of thumb but to day it is not only influenced at every stage by scientific research, but sometimes very costly large scale experiments are made and the industry is ready to try out any new system which offers reasonable expectation of success Very great popular interest was taken formerly in the records of the ships of the 'Atlantic ferry,' the blue riband of which has now been held for twenty two years by the famous *Mauretania* During the coming summer the new German turbine driven liners *Europa* and *Bremen* are due for completion, and it may be that for a time the Atlantic record will pass to Germany as it did some thirty years ago

Apart from the new machinery for very large and fast ships however there are many developments taking place, and a few particulars of recent marine practice may be of value to those who though not directly associated with marine engineering may nevertheless be engaged in the study of some of the numerous problems which are connected with it Marine engineering to day owes very much to the mathematician, the chemist, the physicist and the metallurgist

Confining this article to recent steam practice, it is proposed to give a few notes on up to date boiler work and then refer to some recent improvements in reciprocating engines, steam turbines, and electric transmission gear At first simply great square or oblong boxes with internal flues or with banks of tubes in place of flues, sixty years ago the box boilers gave way to the cylindrical or Scotch boilers, and these have been used until recently almost without exception in merchant ships Such boilers are suitable for steam pressures up to 200 lb or even 250 lb pressure, but with still higher pressures marine engineers have had to follow naval engineering practice and use one or other of the many types of water tube boilers, of which the Babcock and Wilcox and the Yarrow are favourite examples

In the successful working of water tube boilers, a supply of pure water free from grease or scale-forming substances is an absolute necessity In high pressure steam vessels the condenser is

still the Achilles heel of the machinery, and any leakage of the condenser tubes is a source of great anxiety Some of the most interesting boiler installations of recent times are seen in the new vessels of the Canadian Pacific Railway Company, such as the *Duchess of Bedford*, *Duchess of Atholl*, and *Duchess of York* These vessels are driven by steam turbines with single reduction gear Each of them has six Yarrow boilers working at 350 370 lb per sq in with 250° of superheat, and also two Scotch boilers working at 200 lb pressure All the steam from the Yarrow boilers and a part of the steam from the Scotch boilers passes to the turbines, but it is the latter which supply steam to the auxiliary engines Separate condensing and separate feed systems are used, and by this means oil which happens to pass over from the auxiliary engines is prevented from entering the Yarrow boilers Salt and grease in high pressure boilers are things to be avoided at all costs By the use of high pressure superheated steam in these Canadian Pacific vessels, it is expected to be able to reduce the running costs by 20 30 per cent

While the turning of the water into steam, and the condensation of the steam and its return to the boiler as feed water, present the marine engineer with one set of problems involving questions such as the conduction and transmission of heat, the flow of cooling water through tubes and the prevention of deposits and corrosion in condensers and boilers, the burning of the fuel affords ample scope for ingenuity and experiment in another direction Important mercantile steam vessels, like warships, have abandoned coal for oil, but now the possibilities of burning coal in the pulverised state are being explored Reference was made to this by Sir Eustace D'Eyncourt in his paper on "Fuel for Ships," read to the Royal Society of Arts on Dec 5 of last year

Pulverised coal has been used in large boilers in some important power stations ashore for some time, and now in the American ships *Mercer* and *Lingan* and the British ships *Stuartstar* and *Horotata*, various pulverised coal systems are on trial The *Mercer* was the first ship with pulverised coal to cross the Atlantic, the *Stuartstar* is the first British ship to be fitted with a pulverising plant, and the *Horotata* is the largest ship so fitted Many firms have carried out experiments, and it is apparently only a question of time before the main problems of crushing, pulverising, distribution and burning will have been solved There may possibly be a great future for pulverised coal for ships

In the propelling machinery itself, many changes are being made, all with the object of improving economy and reducing running costs The first essential for marine machinery is trustworthiness, but with present-day manufacture and design, few serious breakdowns occur in any of the various types Triple expansion and quadruple expansion engines have been fitted for many years and, in spite of the progress of the steam turbine and the oil engine, the reciprocating engine is found in more ships than is any other engine In triple expansion engines new valve gears are being tried, while a very promising development is the fitting of an exhaust steam turbine in series with the reciprocating engine and coupled to the same shaft through reduction gearing Suggested by Sir Charles Parsons, but introduced first in Germany, this plan is known as the Bauer Wach exhaust turbine system The Anchor liner *Britannia*, a vessel of 8464 tons, built two years ago, has just had such a turbine fitted to her quadruple expansion engines, resulting in an increase of power with a reduction in oil consumption per horse power, and other vessels are being similarly altered, among them being five P and O ships running to Australia via the Cape In view of the large number of ships with reciprocating engines, it may be expected that exhaust turbines will be adopted on a wide scale

Marine engineering has always been influenced by contemporary land practice, but up to the coming of the steam turbine no power station contained machinery comparable in size to that of an Atlantic liner The steam turbine to some extent has reversed that position, but while the largest single unit turbines are found in the super power houses, practice ashore and afloat tends to progress on parallel lines, higher pressures and higher temperatures being used in both cases Then, too, marine steam turbines to day drive the propeller shaft through reduction gearing, instead of directly, or alternatively use hydraulic or electric transmission The introduction of reduction gearing with pinions and wheels with helical teeth cut with extreme accuracy led to a great increase in both turbine and propeller efficiency In a presidential address delivered about two years ago, Engineer Admiral Sir Robert Dixon stated that in torpedo boat destroyers the use of gearing had led to an increase in the distance steamed per ton of oil of 14 per cent at full speed and 70 per cent at cruising speed With the use of gearing came the introduction of the single collar thrust block invented by Michell of Australia, a solution of a difficult problem as complete as it was unexpected In the development of the turbine, the gearing and the thrust block are seen many striking results of the successful application of theoretical investigations to urgent practical problems of ship propulsion

For the transmission of the power of the turbine to the propeller shaft, electricity has been used extensively in the United States Navy, which tried out the system first in the collier *Neptune*, now the aircraft carrier *Langley* This system is also found in about thirty ships with a collective horse power of 500,000 plying on the Great Lakes Much interest was created last year by the performances of the American Panama Pacific Liner *California*, with turbo electric machinery, and in view of the recent completion of the P and O *Viceroy of India* with turbo electric machinery, comparative figures may be of interest Though tried in an experimental launch, the *Electric Arc*, in 1911, and in the s s *Tynemount* in 1912, the electric drive has not previously been fitted in any large British ship, and the running of *Viceroy of India* will be

watched by every superintendent engineer The *California* is 601 feet long and has a gross tonnage of more than 20,000 tons Steam is supplied by oil fired Babcock and Wilcox boilers at 275 lb pressure and 120° F superheat to two turbo alternators, each of 8500 s h p running at 2880 revolutions per minute, which supply current to the twin screw propelling motors running at 120 r p m At full power the vessel has a speed of 18 knots, and the consumption of oil on the first voyage for all purposes was 0 8 lb per h p The *Viceroy of India* is 612 feet long, with a gross tonnage of 19,000 and a displacement of 25,000 tons In her, six Yarrow boilers supply steam at 350 lb pressure to two 9000 k w turbo alternators running at 2700 r p m supplying current to twin screw motors running at 109 r p m The speed of the ship at full speed will be 18¾ knots, while with only one alternator in use a speed of 16½ knots will be obtained It is stated that the guaranteed con sumption for propelling purposes only is 0 6 lb per s h p per hour Besides the main generators, the *Viceroy of India* has four 500 k w auxiliary turbo generator sets and two 165 k w oil-driven sets, while for the pumps, fans, steering motors, etc , which are electrically driven, there are no fewer than forty three circuits This notable vessel is advertised to sail on her maiden voyage on Mar 28 It has been announced that the new 'Super-Olympic' liner building at Belfast for the White Star Line will also have electric drive, but parti-culars of her machinery have not yet been pub-lished

Progress in steam marine machinery has un questionably been stimulated by the growing popularity of the motor driven ship with its sur prising economy in fuel For fast ships and war-ships, however, the steam turbine is at present the only suitable engine, while in other classes of vessels no doubt various types will continue to be used according to circumstances In Lloyd's Register Book the tonnage of ships above 100 tons included amounts to 65,159,413 tons gross, of which 5,432,302 tons are driven by oil engines, 9,682,063 tons by steam turbines, and 50,045,048 tons by steam reciprocating engines, while of the total tonnage 62 4 per cent burn coal and 37 6 per cent use oil either under the boilers or in the engines Some of the steamers fitted for burning oil can if necessary use coal

Obituary

Sir Bertram Windle, F R S

It is with deep regret that we record the death of Sir Bertram Windle, professor of anthropology in St Michael's College, University of Toronto, which took place in Toronto on Feb 14 Bertram Coghill Alan Windle was born on May 8, 1858, the son of the Rev S A Windle, vicar of Market Rasen, Lincolnshire He was educated at Kings town and Repton schools, and had a distinguished career at the University of Dublin, where he gradu ated M D and D Sc He was for a time Dean of the Medical Faculty and professor of anatomy and anthropology at the University of Birmingham He afterwards became professor of archæology in University College, Cork, of which he was appointed president in 1904, holding this office from 1904 until 1919, when he went to Toronto During his residence in Ireland he was extremely active in educational and other affairs, with results that were not always conducive to his tranquillity of mind

In his more strictly professional studies, Windle attained considerable eminence His contribu tions to anthropological literature were marked by originality and freshness of view Besides papers in scientific journals, he was the author of a manual of surface anatomy, now in its third edition, and of "The Proportions of the Human Body," pub-lished in 1892 He was, however, almost as widely known as an archæologist as an anatomist He published several books on prehistoric archæology, of which the best known are "Life in Early Britain" and "The Prehistoric Age" His "Romans in Britain" was of a more popular character and was based on lectures delivered in Toronto He was elected a fellow of the Royal Society in 1899 The breadth of his interests was also shown in a series of literary guide books, of which "Shakespeare's Country" is most likely to be of enduring value

Windle's main preoccupation, however, outside his professional studies, was in religious questions, and especially the relations of religion and science At the age of twenty five he joined the Roman Catholic Church, and by far the greater part of his not inconsiderable literary output was concerned with religion "The Church and Science" was awarded the Gunning Prize in 1917, and Windle was honoured for his writings by two popes, Pius X made him a knight of the order of St Gregory, and Pius XI made him an honorary Ph D

News has just reached us of the death on Jan 17 at Moscow of Dr G S Zaitzev, director of the Turkestan Plant Breeding Station Beginning in 1914, Dr G S Zaitzev devoted himself to serious and large scale genetic, botanical and breed ing work in cotton, occupying the position of the chief of the Division of Plant Breeding of the Golod nostepskay Agricultural Experiment Station until 1919 In 1919 Dr Zaitzev was appointed director of the Turkestan Plant Breeding Station, where he remained until his death, which has interrupted a life full of scientific achievements in our know-ledge of the cotton plant In addition to his work at the Turkestan Plant Breeding Station, Dr Zaitzev was engaged in the U S S R Institute of Applied Botany (Leningrad) as cotton specialist, and in the Central Asia State University (Tashkent) as professor of cotton growing at the Agricultural College By the death of Dr Zaitzev, the Soviet Union and the whole world have lost a distinguished scientific worker in the field of genetics and plant breeding, whose memory will be long preserved and honoured

News and Views.

THE following names of scientific workers and others associated with scientific activities appear in the New Year's honours list, which, owing to the illness of His Majesty the King, was not issued until Mar 1 *Barons* Sir Jesse Boot, for services in the promotion of education, Sir Berkeley Moynihan, president of the Royal College of Surgeons *Knights* Prof J A. Fleming, emeritus professor of electrical engineering, University College, London, Mr G A Julius, chairman of the Council for Scientific and Industrial Research, Commonwealth of Australia, Col T F Purves, Engineer in Chief, Post Office, Mr A V Roe, for distinguished services to British aviation, Sardar Jogendra Singh, Minister for Agriculture, Punjab, Lee ah Yain, Minister for Forests, Burma, *Companion of Honour* Lady Florence Elizabeth Barrett, Dean of the London School of Medicine for Women and president of the Medical Women's International Association *C B* Sir Walter Morley Fletcher, secretary of the Medical Research Council, Dr G F Hill, Keeper of the Department of Coins and Medals, British Museum *C M G* Mr F C Madden, Dean of the Faculty of Medicine, Egyptian University, Cairo *K C I E* Sir Thomas Middleton, lately member of the Royal Commission on Agriculture in India *C I E* Mr R S Finlow, Director of Agriculture, Bengal Mr N N Gangulee, lately member of the Royal Commission on Agriculture in India, Mr J A Madan, lately joint secretary to the Royal Commission on Agriculture in India, Mr W Mayes, Chief Conservator of Forests, Punjab, Mr F W H Smith, lately joint secretary to the Royal Commission on Agriculture in India *G B E* Sir William McCormick, chairman of the University Grants Committee and of the Advisory Council of the Department of Scientific and Industrial Research *D B E* Prof Anne Louise McIlroy, professor of obstetrics and gynæcology, Royal Free Hospital School of Medicine for Women, University of London *C B E* Prof Winifred Cullis, professor of physiology, London (Royal Free Hospital) School of Medicine for Women, Mr R Hewison, late Director of Agriculture and Forests, Sudan Government, Mr W Nowell, Director of the Amani Research Institute, Tanganyika Territory *O B E* Mr G E Hunt, lecturer in engineering, Gordon College, Khartoum, Mr W A Taylor, superintending examiner, Patent Office *M B E* Mr G E Holden, technical adviser to the Dyestuffs Advisory Licensing Committee, Mr A J W Hornby, agricultural chemist, Nyasaland Protectorate

WE publish elsewhere in this issue a résumé of a detailed research on the performance of ammeters and voltmeters made by the British Scientific Instrument Research Association, of which the director is Sir Herbert Jackson The research is of a somewhat novel type, but there can be no question about the usefulness of this kind of research to industrial undertakings, and we hope that it will be widely followed The research was initiated by some members of the Association, who were naturally disturbed by the disparaging remarks made by a few station engineers about British switchboard instruments They desired that a critical examination be made of the operation, appearance, and permanent qualities of British and foreign ammeters and voltmeters for use on switchboards in central electrical stations In order to bring the research within manageable limits it was restricted in the first place to permanent magnet moving coil instruments The research was to be impartial and thorough, the best foreign and British instruments being obtained from well known makers

THE results of this investigation of British and other ammeters and voltmeters are satisfactory from the point of view of the British manufacturers Naturally there is much in the detailed report which is confidential to members of the Association, but the synopsis proves conclusively that their products were at least as good as those of their American and continental rivals The greatest value of the report, however, lies in the criticisms made freely about all the instruments and the reasons given why certain makes are more desirable than others These criticisms should prove most useful to the designer As a rule, design is largely a compromise the better the instrument is made in one respect the worse it is in another It is largely a balancing of incompatibilities, and the successful maker is the one who secures the best balance The nature of the materials used for the instruments has been examined, and such questions as to the relative merits of aluminium and copper wire for use in winding the coils is fully discussed To manufacturers this kind of research is of the greatest value, and we congratulate the Association on its report

REFERENCE is made in the *Times* of Mar 2 to a biennial fibre plant to which the name 'Brotex' has been given The plant is being grown on a small scale near Totnes in South Devon, and it is claimed that in less than eighteen months from planting it will produce fibre for textiles, cellulose for paper making, and seed containing oil suitable for cattle food That a plant with so many desirable qualities, which will survive the winter in the south of England, should only now have been brought to notice, is somewhat remarkable and merits further investigation It is stated that the plant grows to a height of about 10 feet in the course of 15 18 months, but nothing is said as to the soil exhaustion that is likely to take place with a crop of this kind, nor is it pointed out that land suitable for such a crop is somewhat limited in the south west of England

THE "evolution of the plant" has not been disclosed, pending application for patents, though it has been stated elsewhere to be of hybrid origin It is known, however, that it belongs to the genus *Lavatera* of the family Malvaceæ, and the plants now being grown in Devonshire very closely resemble a species which is a native of the Canary Islands, a plant which would certainly be hardy only near the warm south-

west coast of England in normal winters The mallow family contains many well known fibre yielding plants, such as *Abutilon Avicennæ* (the source of Chinese jute), *Hibiscus cannabinus*, *Sida rhombifolia*, etc, and in some cases the seeds are also of value for cattle food None of these plants is hardy in Great Britain, and even *Lavatera arborea*, which is the only *Lavatera* found in England, will only succeed well near the coast If, therefore, 'Brotex' can be proved to be of hybrid origin, not only will it be of scientific interest to know its parentage, but it will also be of material importance to know whether it will regularly produce fertile seed in Great Britain Moreover, it is of importance, from the commercial aspect, to know whether the fibre is superior to jute and hemp, with which fibres we understand the market is already fully supplied

A TIMELY article by Sir Oliver Lodge appears in *The Nineteenth Century* for March on the philosophy of "the genius who now lives among us and whom we call Eddington," as expressed in the latter's recent book, "The Nature of the Physical World" After expressing his agreement with the greater part of Eddington's thesis, Sir Oliver proceeds, in a perhaps unnecessarily apologetic manner, to deal with one or two contentions against which, as he expresses it, "I politely and reasonably rebel" The points which he discusses are respectively the tendency to regard the subject matter of science as confined to quantities which can be measured, and the abandonment of the notion of force in the descriptions of field physics On the second point Sir Oliver affirms his belief in the reality of a physical force exerted by the strained ether on a body placed in a gravitational field Eddington, in company with all orthodox relativists, prefers to express the facts in terms of the geometrical properties of the field To a large extent, if not wholly, the difference here is merely verbal, but the first point, concerning the essential character of science, deals with more fundamental issues The suggestion that phenomena or ideas which cannot be measured are not amenable to scientific treatment has taken immediate root in the minds of philosophical writers, and its foliage seriously threatens the survival of the finer blooms of thought which have been reared with much greater difficulty

THE simplicity of this false generalisation has gained for it a rapturous welcome from philosophers bewildered by the headlong advances of modern physics, and the relations between science and religion in particular are in consequence viewed in an entirely false light The subject matter of science is the common experience, obtained through the five senses (the so called *observations*), of the generality of observers The purpose of science is to record and correlate such observations Measurement may—in fact, does—assist both the recording and the correlation, but it does not dominate them It is not, for example, exclusively employed—nor can it probably ever be—in recording the behaviour of a spider placed in a hive of bees, or in correlating the movements of swallows with the declination of the sun, yet these activities are certainly fair game for scientific investigation A careful perusal of Eddington's book will show that it contains no specific warrant for the misconception, but if, as we believe, a writer of outstanding authority should guard as much against misinterpretation by the casual as by the meticulous reader, he can perhaps not be wholly absolved from responsibility for its prevalence That, however, is of secondary importance What is chiefly to be desired is that the true nature of science shall be clearly understood, and Sir Oliver Lodge's article should help considerably towards this end

THE eighth Annual Report of the National Institute of Industrial Psychology shows a steadily progressive increase in the interest taken by firms in the application of the principles of physiology and psychology to industry The range of the Institute's investigation services during 1928, as judged by the fees received, has expanded by 29 per cent in comparison with the previous year A most diverse array of activities is represented by the list of investigations, which include spinning, the manufacture of electric light fittings, pickles jam, and soap the selection of staff and the layout of large stores, to mention but a few There has also been growth in the other departments of the Institute's work, for example, in vocational guidance, research, and education It is hoped during 1929 to inaugurate a new department for the purpose of applying to the problems of the home those principles which have been found useful in other fields The second part of the report gives an outline of some of the investigations undertaken during the year The third part records the research work for the year, this includes experiments in vocational guidance in London and Fife, an inquiry into occupations suitable for the blind, and a varied number of researches initiated or continued with the grant given by the Laura Spelman Rockefeller Memorial It is clearly a record of most important and useful work

PROF J REILLY and D T MacSweeney give an account, in the *Proceedings of the Royal Dublin Society* for January, No 15, of the work of William Higgins, whose book, published in 1789, "A Comparative View of the Phlogistic and Antiphlogistic Doctrines," contains some interesting speculations on chemical combination The work is the first defence of the new views of Lavoisier in the English language and was written in answer to Kirwan's "Essay on Phlogiston" Higgins' work, according to Reilly and MacSweeney, contained the fundamental germs of the chemical atomic theory, and had it not been neglected it would have led to much that Dalton afterwards put forward It is to the genius and industry of Dalton, and the encouragement and friendly criticism of his contemporaries, that the main credit for the establishment of the theory must be ascribed Higgins' work (which is based on experiment and is by no means purely speculative) is particularly interesting in its attempt to represent affinities as well as combining proportions, a side of the subject which was, perhaps wisely, entirely

Reviews.

Population and Depopulation

(1) *The Balance of Births and Deaths* Vol 1 *Western and Northern Europe* By Robert R Kuczynski (The Institute of Economics of the Brookings Institution) Pp xii+140 (London George Allen and Unwin, Ltd, New York The Macmillan Co, 1928) 10s net

(2) *The Shadow of the World's Future or the Earth's Population Possibilities and the Consequences of the Present Rate of Increase of the Earth's Inhabitants* By Sir George Handley Knibbs Pp 131 (London Ernest Benn, Ltd, 1928) 10s 6d net

AT the World Population Conference held at Geneva in 1927, one might observe a contrast in viewpoint of the very greatest interest The delegates from the United States were much concerned with the imminence of the dangers of over population, while the majority of European speakers, at least those who spoke with authority on their own national statistics pointed out in almost monotonous succession that their birth rates either had already fallen or would soon fall below the level necessary to maintain stationary populations Generally speaking, northern Europe has seen the end of the period of population expansion Is it possible that the American average of 39 to the square mile is more impressive of over population than the European average of about 300?

In the preface to his book, Sir George Knibbs says (p 5)

" it shows that the menace of the present rate of growth of those inhabitants is most serious This rate is of the order of about 1 per cent per annum"

Mr R R Kuczynski, on the contrary, remarks in his introduction

"In case, then, that natality does not again increase, the population of England is bound to die out no matter how low mortality may be reduced And this state of affairs is by no means confined to England Conditions are about the same in Germany, and only slightly better in France"

The scope of the two books is very different Sir George Knibbs considers the earth as a whole, Mr Kuczynski takes northern and western Europe, while succeeding volumes of his series will deal with other regions "The Shadow of the World's Future" is to influence national policies in respect of population, migration, and food production "The Balance of Births and Deaths" is concerned with a detailed statement of the relevant statistical facts, collated for the whole group of countries considered It confines itself strictly to the existing tendencies in the growth or decline of populations, whereas the rate "of the order of about 1 per cent per annum" is practically the only statement on this subject which seems necessary for 'The Shadow of the World's Future" One book is scientific, the other, political

(1) To take the scientific book first It has four short chapters on 'Birth Rates," "Fertility Rates," 'Net Reproduction Rates," and "Present and Future Tendencies," followed by four long, and largely tabular, appendices Fertility rates are birth rates based on the numbers of women actually available for reproduction They lead to gross reproduction rates giving the number of live daughters born per woman For 1927 the value for Germany has fallen to 1 00 and for England to 0 98 Even with no mortality in infancy and childhood these figures are incompatible with biological increase For the whole area in 1926 the value is 1 12

In the net reproductive rates allowance is made for mortality, the figures may, in fact, be read as the actual births expressed as percentages of those needed to maintain a stationary population The estimates for 1926 are for England 88, Germany 89, France 94, Sweden 95, Denmark 110, Finland 109, and for the whole area about 93 These values also are falling rapidly, for in 1927 the estimates are France 91, Germany 83, England 82

The main points, which are being but slowly apprehended in Great Britain, are brought out with perfect lucidity For example, that the present populations have an unusually large proportion of persons of reproductive age, and unusually few of the elderly, that the course of the changes in

reproduction has not been appreciably changed by the War, and that, since the mortality rates of persons above the reproductive age are without effect upon future population growth, the present tendencies to decreasing population can only be appreciably altered by increasing fertility

(2) Sir George Knibbs's fears seem to be centred upon somewhat improbable prospects of the increase in the world's population He allows that the earth's resources, if wisely exploited, would support about 7800 millions of human beings This seems a very handsome allowance, being four times the total existing world population Trouble is anticipated (p 118) from "the mere increase in population, coupled with the fact that Man's moral development has not kept pace with scientific knowledge" The threatening shadow sometimes takes the appearance of a bogy (p 119)

"We are rapidly approaching numbers that make the problem a stupendous, aye, an appalling one"

Should 2000 millions induce more stupor than 1900 millions?

The chapter on the world's cereal and food crops is of course written on the assumption that there is an immediate prospect of the demand for food outrunning the supply No evidence is adduced that this is so, and the evidence to the contrary is ignored entirely It might be strongly argued that the situation at present and the prospects of the immediate future indicate a systematic over production of foodstuffs Agriculture throughout the world is a depressed occupation in the sense that the worker on the land works harder for a lower economic recompense than the worker in any other industry In agriculture the crops which pay best are either luxury foods or not food crops at all Falling food prices have caused an increased consumption per head in most countries but the increase is naturally least in the staple foods and greatest in the delicacies What agriculture needs is higher prices for staple foodstuffs, relatively to the cost of buildings, clothes, and machinery, but with new areas still apparently yearning for agricultural development, the prospect of better prices is far off It has indeed been calculated that the rate of increase in the supply of fixed nitrogen as fertilisers would more than suffice to meet the present rate of world population increase without putting a single new acre under cultivation However this may be, the supply of foodstuffs is elastic enough, it is the demand that is inelastic From Sir George Knibbs's point of view it is, however, worth while discussing the most extravagant methods of increasing yields (p 40)

" but it has recently been shown that greatly increased yields are at least temporarily attainable with cereals by transplanting The increased yields are due to the greater root development thus obtained The use of carbon dioxide has also led to higher yields In any case these results, *while they relieve the outlook for the immediate future* [Reviewer's italics], do not warrant any disregard for the outlook resulting from population increase"

While such diversities exist in intelligent opinion as are shown by these two books, there can be no doubt of the need for bodies devoted to eliciting the real facts, such as the British Population Society, for the parent international body of which Sir George Knibbs puts in a warm plea

R A FISHER

Old English Versions of Alchemical Texts

The Works of Geber Englished by Richard Russell, 1678 A new edition, with Introduction by Dr E J Holmyard Pp xl+264 (London and Toronto J M Dent and Sons, Ltd, New York E P Dutton and Co, Inc, 1928) 6s net

ENGLISH scholars first became interested in the translation of alchemical texts in the twelfth century, when they participated with the celebrated Gerard of Cremona and other continental scholars in making known to western Europe the accumulated wisdom of the Muslim world Prominent among them were Adelard of Bath, Walcher of Malvern, Roger of Hereford, and Robert of Chester, the last named of whom, according to tradition, first introduced chemistry into Europe "Since," wrote Robert, in the preface to his first translation of an Arabic alchemical treatise, in 1144, "your Latin world does not yet know what alchemy is, I will explain in the present book" The translations of this period were of course done into Latin, and the same language was the usual medium in which the adepts embodied, or embedded, their observations and ideas throughout the succeeding five centuries

The "Speculum Alchemiæ" of Roger Bacon, the earliest alchemical work of any note by an English author, was first translated from Latin into English in 1597, it appeared under the title "The Mirror of Alchimy," and is now very rare Printed in company with Bacon's "Speculum" and other works, in such editions as those dated 1541 (Nuremberg) and 1545 (Berne), were certain Latin texts ascribed to Geber (Jabir) These texts, which can be traced back through the first printed edition of about 1481

to manuscript versions of the early thirteenth century, were first translated into English in 1678 by Richard Russell, under the title "The Works of Geber, The Most Famous Arabian Prince and Philosopher Faithfully Englished by R R a Lover of Chymistry" The English translation was reprinted in 1686, and it has now attained the distinction, after an interval of exactly 250 years from its original publication, of appearing in a third edition, enriched with reproductions of the bold woodcuts of alchemical apparatus which embellished the Latin edition of 1545

In an interesting preface, Dr Holmyard points out that no Arabic originals of the text are known, so that its authenticity is unproved After considering the available evidence bearing upon the origin of the writings, he reaches the conclusion that 'whatever the future may disclose concerning them, we may safely say that they are not unworthy of Jabir and that he is worthy of them, and that we know of no other chemist, Muslim or Christian, who could for one moment be imagined to have written them" The main sections of the book are entitled "Of the Investigation or Search of Perfection," 'Of the Sum of Perfection, or of the Perfect Magistery," "Of the Invention of Verity, or Perfection," and 'Of Furnaces, etc, With a Recapitulation of the Authors Experiments"

Possibly the most interesting part is the account "of the Natural Principles of Metals, according to the Opinion of Modern Philosophers, and of the Author,' of "the Three Principles, viz Sulphur, Arsenick, and Argentvive," and of the six "Metallick Bodies, which are the Effect of these Principles of Nature' The description of sulphur as "a fatness of the Earth" is suggestive of the statement of Paracelsus that "the life of Metalls is a secret fatnesse, which they have received from Sulphur, which is manifest by their flowing" The second principle, Arsenick, "needs not be otherwise defined than Sulphur But it is diversified from Sulphur in this, viz because it is easily a Tincture of Whiteness, but of Redness most difficultly and Sulphur of Whiteness most difficultly but of Redness easily" The third principle, Argentvive, or Mercury, "is a viscous Water in the Bowels of the Earth It is also (as some say) the Matter of Metals with Sulphur And it easily adheres to Saturn, and Jupiter, and Sol Therefore hence you may collect a very great Secret For it is amicable, and pleasing to Metals, and the Medium of conjoyning Tinctures"

The metals are described in vivid terms, which suggest a close acquaintance of the writer with their properties Gold is "Citrine, ponderous, mute, fulgid under the Hammer extensible, fusible, and sustaining the Tryal of the Cupel, and Cement" Silver is "White with pure Whiteness, Clean, Hard, Sounding" Lead is 'livid, earthy, ponderous, mute" Copper and iron are characterised with equal felicity, finally,

"not omitting to discourse of Jupiter, We signifie to the Sons of Learning, that Tin is a Metallick Body, white, not pure, livid, and sounding little, partaking of little Earthiness, possessing in its Root Harshness, Softness, and Swiftness of Liquefaction, without Ignition, and not abiding the Cupel, or Cement, but Extensible under the Hammer Therefore, Jupiter, among Bodies diminished from Perfection, is in the Radix of its Nature of Affinity to the more Perfect, viz to Sol and Luna, more to Luna, but less to Sol, as shall be clearly declared in the following Jupiter, because it receives much Whiteness from the Radix of its Generation, therefore it whitens all Bodies not White, yet its vice is, that it breaks every Body, but Saturn, and most pure Sol And he who knows how to take away its Vice of breaking will suddenly reap the fruit of his Labour with joy"

These quotations serve a twofold purpose In the first place, they afford an indication of the views upon the constitution of the metals which prevailed, with unimportant modifications, from the time of Jabir (c 721–813) for a period of nearly a thousand years Secondly, they illustrate the peculiar fitness of the seventeenth century mind for interpreting, and recording in the vigorous English of the day, the philosophy, the mysticism, and the superstition of the alchemists, from Jabir to Paracelsus and Glauber Thus, Richard Russell imparts alike to the "Works of Geber," to "Beguinus his Tyrocinium," and to "the Triumphant Chariot of Antimony, with Kirkringius his Notes thereon," the same archaic flavour and picturesque charm which Lord Berners infused in the preceding century into his English version of Froissart's "cronycles of Englande, Fraunce, Spayne, Portyngale, Scotlande, Bretayne, Flaūders, and other places adioynynge"

A similar atmosphere permeates the writings of Russell's contemporary, John French, the translator of Glauber, Sendivogius and Paracelsus, and of "a Chymicall Dictionary explaining hard places and words met withall in the writings of Paracelsus, and other obscure authors" "Are not Philosophers," asks French in his introduction to Glauber's "Description of new Philosophical Furnaces," published in 1651, "the best moralised men, of the purest lives, and most serviceable in their generation? It shall be my practise as long as I

live to be instrumental in promoting true knowledge, whether by way of Translation or any other way of making what is occult manifest "

Boyle's "Sceptical Chymist" (1661) marked alike the decline of alchemy and the gradual abandonment of Latin by exponents of the new chemistry which was to arise Nevertheless, Walter Harris and others continued the tradition of the seventeenth century translators, and no true "Lover of Chymistry' would willingly forgo such passages as Boyle's own quotation of the experience of the Dutch sailors at Nova Zembla with a barrel of frozen beer in the winter of 1596, and Harris's description, in his Englished version of Lemery's "Cours de Chymie,' of the rectification of spirits of wine, to which end, he says, "Artists have invented a long Machine, which they call the Serpent, by reason of the circumvolutions which it makes"

Dr Holmyard has earned the gratitude of the present generation of "chymicall Artists" by placing such rare classical works as Russell's 'Geber and Norton's Ordinall within their reach May we not persuade him to complete the "tria prima by preparing a new edition of Roger Bacon's 'Mirror of Alchimy'—for, in the words of John French, it is pitty that such useful and so learned writings should be obscured from the English Nation'

Homing among Animals

How Animals Find their Way About a Study of Distant Orientation and Place Recognition By Prof Étienne Rabaud Translated by I H Myers (International Library of Psychology, Philosophy and Scientific Method) Pp ix + 142 (London Kegan Paul and Co, Ltd New York Harcourt, Brace and Co, Inc, 1928) *7s 6d* net

DURING the present century the solution of the problem of 'homing,' or orientation from a distance, has come within sight, for backboneless animals at any rate, and the reason for the progress is to be found in the resolute use of experiment For bees and wasps it seems quite certain that they cannot find their way home unless they have had some experience of the locality, and unless hey can see well during their return flight Bees liberated on a lake near the hive do not return, unless by chance, for there are no landmarks to guide them The cues utilised by bees and wasps are visual, by following these they retrace the path they travelled in leaving the hive or nest But there is evidence that the cues are relations between objects rather than the objects themselves There seems to be a co ordination of clues into what might be called a synthetic impression—what would be in our case a mental picture, and there may be a successful bee line for the hive though various intermediate cues disappear

After many journeys the insect becomes more confident, it is even probable that muscular memory may be substituted for visual cues over a large part of the course When the bee is near the hive, olfactory, tactile, and perhaps other cues come into play But, according to Rabaud, the homing of flying Hymenoptera depends mainly on visual cues, and it is quite unnecessary to postulate any special sense of direction The experiments referred to convince one that this must be on the whole a sound conclusion

In the pedestrian ants the cues are more heterogeneous Olfactory hints are most important for those that travel in columns Visual cues intervene when the trail is accidentally destroyed

"As for isolated ants, they follow simultaneously visual cues of various kinds—light and large objects—closely associated, and connected in addition with features of the ground, notably with the slope Every cue is associated with all the others and also with the topographical position of the nest"

There seems to be a registration of the topography as a whole, for on the return journey the experienced ant may neglect roundabout paths and take short cuts In the course of time the return perhaps becomes a matter of kinæsthesis and appreciation of distance But, as in the case of bees there is no warrant for postulating any special sense of direction

Among the blind termites a trail is left by the troop and the cue is altogether olfactory If the path is swept, the termites are completely disoriented In limpets the return to the habitual position is mainly due to tactile cues For all invertebrates that show any homing,' the facts can be satisfactorily interpreted in terms of visual, olfactory, tactile, and baræsthetic or kinæsthetic cues

In regard to vertebrates, the conclusions are less secure, for fewer experiments have been made The most satisfactory data are in regard to carrier pigeons, but the case is complicated by the gradual training which the birds receive from man They can find their way home from a distance of several hundred miles, and when they did not themselves make the particular outward journey The evidence for a special magnetic or electromagnetic sensi-

tiveness is very dubious, the theory that the bird registers its outward journey in detail, and then retraces its steps, has to face the difficulty that the pigeons are often taken to a distance by train, Rabaud favours the view that the pigeons during their period of training acquire a considerable knowledge of places and utilise this experimentally on their return journey, even from a region not previously visited There are, however, some alleged returns on the part of untrained carriers, but these might be fortuitous

Against the possibility of homing without experience, it is perhaps enough to notice that in many cases the travellers from a great distance fail to return at all In 1895 five thousand pigeons were released at sea at varied distances west of Croisic The number of returns and the speed of the returns diminished with the distance and the altitude increased Out of 1500 pigeons released at 500 kilometres, 300 returned within forty eight hours—a sufficiently remarkable fact, the others were found scattered everywhere in England, Spain, Portugal, Algeria, at Cape Verde, in Egypt, and in the Caucasus Very significant is the fact that the return journey often takes far too long for the distance involved Thus eight pigeons, ignorant of the particular route, were transported from Antwerp to London

"Released at six o'clock in the morning, in fine weather, they turned about for a long time, and then flew off and had returned to Antwerp by seven in the evening, having taken thirteen hours to accomplish a journey normally requiring barely three"

This points strongly to the conclusion that whenever there is difficulty in the return journey, because of inexperience, absence of landmarks, bad weather, darkness, or the like, there is much tentative flying on the carrier pigeon's part The more the groping bird flies about, the greater is its chance of finding some cue

In the well known experiments made by Watson and Lashley on the terns nesting on the Tortugas, a percentage of birds returned from great distances, even of 800 miles, and from previously unvisited waters into which they had been transported in closed baskets on board ship But the successful return journeys took an unnecessarily long time

It is regrettable that the cases of homing on the part of domesticated animals, such as cats, dogs, horses, cattle, and sheep, remain at an anecdotal level "A cat taken by rail from Fife to Ayrshire was back again in two or three days", there are many such unprecise records, which should be tested experimentally There would certainly be some interesting result

Prof Rabaud has written a useful book on an interesting problem, and though, for our part, we should not wish to hurry to a conclusion, we admit that he has made out a strong case in favour of interpreting all homing in terms of a memory or registration of sensory cues His book is a good example of scientific scepticism and caution, and it badly punctures the hypothesis of a special sense of direction Yet when we think of the most recent experiments on homing bees, the average success of ordinary bird migration, and such striking cases as the return of a swallow from Africa to the Aberdeenshire farm steading where it was born the year before, the work of Watson and Lashley on terns, and the stories we have heard of homing cats, we are glad that Rabaud does not consider the question entirely solved

General Science for Schools

(1) *General Science (Mainly Chemistry and Biology)* By Dr E J Holmyard Pp xiii + 236 (London and Toronto J M Dent and Sons, Ltd New York E P Dutton and Co, n d) 4s

(2) *Everyday Science a Course of General Science related to Human Activities* By Dr L M Parsons Pp xi + 695 8s 6d Also in parts I, The Sky, the Earth, and Life II, Physics Man's Use of Motion III, Chemistry Man's Use of Matter 3s each (London Macmillan and Co, Ltd, 1929)

(3) *Junior Science* By C A Stebbins Pp xii + 352 (New York The Macmillan Co, 1928) 6s

(4) *Introductory Science for Botany Students* By K E Maris Pp vii + 181 (London John Murray, 1928) 3s

(5) *The Romance of Reality the Beauties and Mysteries of Modern Science* By Dr Beverly L Clarke Pp ix + 225 (New York The Macmillan Co, 1927) 10s net

(1) FOR years past, teachers have been saying that in the early stages science should be taught in a general way that historical treatment is desirable, and that the lessons should be of the object study sort It is to be hoped that they will like Dr Holmyard's book, for here they have it all presented in an ideal manner The author has excelled himself as historian and philologist, and the wine of his science teaching requires no bush His volume is intended as a second course, between an introduction and more formal study, but it is to be

feared that it may prove rather difficult at that stage For the sixth form boy who wishes to link up his science with history and with classical lore, and vice versa for the history and the classical specialist, it should suit perfectly Indeed, the science teacher himself who failed to derive pleasure from reading the pages would have to be either an exceptionally clever or an exceptionally dull person For this reason, if for no other, the book is to be commended to his notice

(2) Differing entirely from the foregoing in its method of treatment, the really excellent book which Dr L M Parsons has written should make an equally wide appeal It seems exactly suited to the general reader who desires a knowledge of the operations of natural phenomena or of the principles and applications of science Primarily the book is designed for students at school, but the author has avoided any suggestion of writing down to immature minds, and the work everywhere demands intelligence and concentration from the reader There are three parts, the first dealing with astronomy, geology and biology (including man), the second with physics, and the third with chemistry The last section, very naturally, makes rather more difficult reading than the other two, but throughout there is a singleness of aim and a lucidity of presentation which cannot fail to secure appreciation It may even do more and succeed in luring some of the rigid formalists among teachers from their straight and dusty paths

(3) As in the case of the two books previously mentioned, Mr C A Stebbins, though approaching the problem at a different angle, makes an attempt —and a good one—to instruct the young in natural science, through their interest in the things which surround them Devoting more space to the biological than to the physical aspects, the ground is reached through such pursuits as gardening and poultry farming The chapters on botanical subjects are exceptionally good, and contain useful descriptions of simple experiments on plant physiology This book also is to be commended for consideration by those who wish to get out of the usual rut in teaching science to beginners

(4) The intention of the author of the fourth book on our list is that it is to be studied as concurrent aid to a course in botany Although she is right in asserting that the usual text-book of elementary science is designed either as a preliminary to more advanced study of chemistry and physics or merely as an introduction to the subject with no definite end in view, her own aim has not always been very steady If her book is meant as an introduction to botany, much is included which might have been omitted, and on the other hand, it is not always of a sufficiently elementary character to serve as a 'first reader' We confess to a liking for books which have no ulterior end in view, and in our childhood that liking was even stronger It is so satisfying to feel—even if it is not true—that the book we are reading begins at the bottom and finishes at the top All of which is not to say that there are not many good things in the present book, for there are But the ideal school-book is one which can be read without help and gives the same sort of satisfaction as a dinner which has run through all its courses and has not stopped short at the fish

(5) Dr Beverly Clarke's purpose in writing differs from all those whose books have been mentioned above, for his immediate aim is, not so much to teach science as to show to those who are in outer darkness the beauties which can be revealed in the light of scientific knowledge In treating of many diverse themes, from protozoa to relativity, he manages to avoid mathematics entirely, and so has frequently to fall back on analogy for elucidation To the erudite this method may seem tedious and even unscientific, but doubtless it may help the unlearned, for whom he writes, to understand a little, and perhaps to marvel much

Quantum Mechanics

Materiewellen und Quantenmechanik eine elementare Einführung auf Grund der Theorien de Broglies, Schrödingers und Heisenbergs Von Prof Arthur Haas Pp vii + 160 (Leipzig Akademische Verlagsgesellschaft m b H, 1928) 7 50 gold marks

Wave Mechanics and the New Quantum Theory By Prof Arthur Haas Translated from the German edition "Materiewellen und Quantenmechanik" by L W Codd Pp xviii + 124 (London Constable and Co, Ltd, 1928) 7*s* 6*d* net

IT is now just three and a half years since quantum mechanics came into conscious being—or rather more than five years if we should date it back to the material waves of de Broglie The new theory has changed and expanded with such rapidity that even the bravest and most industrious writers have shrunk until now from the task of systematic exposition Now, however, books on the new theory begin to come to hand, and in the near future we may expect them in increasing numbers

Books which can properly be called books on quantum mechanics, or for that matter on any important new theory, are of three types (1) Systematic expositions which adopt a single consistent point of view and attempt, however imperfectly, whether in an elementary way or with elaborate mathematics, to develop the theory from that point of view as a logical whole, (2) reprints or translations of original papers by the main authors of the new theory, (3) books of an introductory or miscellaneous character, usually of the nature of, if not actually, courses of somewhat disconnected lectures Books of the first type are welcome in any numbers, however great The principal difficulty at the present stage is not how to use quantum mechanics but how to talk about it most intelligibly This is strikingly shown by the fact that many physicists, some of whom should know better, still speak of wave mechanics, matrix mechanics, and even the q number mechanics of Dirac as if they were three distinct theories instead of merely three different ways of trying to expound the same theory

It is likely that it is only by repeated attempts at systematic exposition that we shall achieve intellectual contentment about the new theory The first book of this type in point of time is Weyl's "Gruppentheorie und Quantenmechanik"—likely to remain for a long time to come a very notable example The great abstractness of its mathematical form is its outstanding feature and probably the main source of its more permanent importance But most of us, if we are honest with ourselves, though we may admit the importance of such abstractness, will admit, too, that we are as yet scarcely educated up to it The other book of the first type which has already appeared—Sommerfeld's "Wellenmechanischer Erganzungsband" to his "Atombau und Spektrallinien"—which expounds the theory systematically from the starting point of Schrödinger's wave equation—will prove to many of more immediate practical assistance We await with interest the many other systematic expositions of which there are rumours, confident that most of them will help to clarify our modes of thought and speech about atomic physics

Books of the second type of course tell us nothing new They are obviously a convenience to many students, especially in translation We welcome for this reason the recent publication of translations of the original papers of Schrödinger and of selected papers of Brillouin and de Broglie In spite of this convenience, however, it is questionable if there is not an element of danger to the student in the immediate publication of collected papers in book form A book is a much more imposing thing than a few offprints, and is liable to be given an authority which its contents do not warrant It is clear from his preface that no one is more fully alive to this danger than Schrödinger himself

Books of the third type may obviously range in value between very wide limits At their best they have very much of the nature of books of the second type, with the added advantage that the material has been worked through by another mind Birtwistle's "New Quantum Mechanics" is a book of this type, giving a convenient and faithful but uncritical reproduction of much of the earlier work on the theory Another better example is Haas's "Wave Mechanics and the New Quantum Theory," which in the original and in translation is the occasion for this essay This book is definitely not a systematic account of the new theory it is fairly elementary—would that it were systematic too! But it does give an excellent account of various disconnected aspects and applications The translation seems to be well done there are one or two obscurities due to failure to use the accepted English equivalent for a technical mathematical term, but they are not serious, and slips and misprints are very few It is likely to prove quite a useful book

Bushmen of the Central Kalahari

The Naron a Bushman Tribe of the Central Kalahari By D F Bleek (University of Cape Town Publications of the School of African Life and Language) Pp ix + 67 (Cambridge At the University Press, 1928) 6s net

ALTHOUGH the School of African Life and Language has been established in South Africa for a few years only, it has already accomplished much useful work in research It has now turned to publication It is appropriate that the first of a projected series of studies of South African tribes should be written by Miss Bleek, for, herself a distinguished authority, she worthily carries on the tradition of a name which will always be associated with the study of South African philology and ethnology Miss Bleek's book, apart from its intrinsic interest, is noteworthy in that it embodies material of a report of an investigation which was undertaken at the request of the Government It is gratifying to note this official recognition of the fact that these tribes present a problem which is worthy of scientific study

Miss Bleek classifies the Bushmen of the Kalahari

into northern, central, and southern The Naron constitute the central group. In structure and in the roots of the vocabulary their language shows affinities with the Nama tongue, but Miss Bleek considers that the differences are sufficient to warrant regarding them as two languages of one group, rather than as two dialects of one language This is not the only respect in which they show Hottentot influence It appears in their culture, in their religious belief, and in their physique Certain elements in culture and physique also show Bantu influence An obvious instance of the former is the custom of throwing the bones or dice as a method of divination in common use, but on a more elaborate system, among Bantu peoples of South and South Central Africa as a method of divination and witch finding It is evidently an importation among the Naron, for Miss Bleek says they seem to know very little about it

The religious beliefs of the Naron are confused and evidently composite Hottentot belief is clearly responsible for their hazy views of a supreme being, and Miss Bleek is more than probably correct in thinking that the original form of their religion was worship of the moon, which, by the way, as so often is regarded as masculine The medicine man, who is both magician and doctor, holds no special position Quarrels among medicine men lead to the use of 'grass arrows,' imitation arrows four or five inches long These, when thrown blunt end foremost, against the opponent's karos, cause death by magic

Miss Bleek's record is one of change, of disintegration, rather than degeneration, thanks perhaps to the fact that they have no intoxicating liquors, not even Kaffir beer They no longer have chiefs, though the older men remember them Originally nomad hunters, the game laws are forcing them to become vegetarians, though they retain their nomadic habits of wandering from water hole to water hole in small groups For they do not cultivate, and have no cattle Marriage was by capture, of which only a vestige remains The only regulation appears to be that brother and sister may not marry, and polygamy is permissible, though not general Of their mentality, Miss Bleek speaks favourably, also of their capacity for work It is clear that their extinction is by no means inevitable, given patient training, and a sympathetic understanding of their inability to endure long uninterrupted periods of employment, which would make it possible for them to supplement their present mode of subsistence, bound sooner or later to prove inadequate

The School of African Life and Language is to be congratulated on its first publication Such an excellent beginning should encourage some generous benefactor to supplement the funds, which are at present inadequate to meet the cost of publication on a more extensive scale

Heat for Students

Heat and Thermodynamics By Dr J K Roberts Pp xvi + 454 (The Student's Physics, Vol 4) (London, Glasgow and Bombay Blackie and Son, Ltd, 1928) 30s net

AN advanced text book upon heat has been urgently needed Most of the literature available for honours students which dealt with the wide range of topics that are included under this title has either been too elementary or too specialised, and, in particular, it has been impossible to refer them to any good account in English of the many accurate experimental researches of recent years, whilst it is admittedly important that they should consult original papers occasionally, the pressure of preparation for examinations does not permit of extensive reading of this nature Dr Roberts's book fills the gap in a student's library that was present as a result of this state of affairs, and provides in a single volume a reasonably complete account of both the theoretical and experimental aspects of the subject

The first eleven chapters are mainly concerned with thermal measurements and such theoretical matters as are directly connected with them Thermometry, the properties of gases, calorimetry, thermal expansion, and the transfer of heat are dealt with more or less in the usual order, but with a range and detail that is new, and makes excellent reading Considerations of space have made it necessary to omit details of some important and accurate experiments that would find a place in a larger treatise, but Dr Roberts's choice of typical experiments of each class, based as it is upon his own experience at Teddington and elsewhere, is that of an expert It is satisfactory to find in this connexion that whilst most weight has naturally been given to recent work in which high precision was the objective, the classical researches of Andrews, Regnault, Rowland, and others have not been entirely ignored The work of Laby and Hercus on the mechanical equivalent of heat appeared too late for description in full, but the methods and results have been given in outline. The only important alteration that might be desired in these earlier chapters, in fact, is the pro-

vision of even fuller accounts than have been given of the properties of bodies at very low temperatures, and the ways in which they have been studied, the relevant original publications are scattered, and those emanating from Leyden, in particular, are not to be found in all science libraries

The remainder of the book is devoted to the more theoretical aspects of heat, thermodynamics being represented by seven chapters, and radiation and quantum theory by three The thermodynamics has been developed from the two fundamental laws, without recourse to the methods of statistical mechanics Certain sections are not given so fully as in Preston's "Theory of Heat," which could scarcely be improved upon for its treatment of general principles, but Dr Roberts has succeeded in presenting thermodynamics as a useful physical tool, and not as a mere branch of mathematics, more than fifty pages, for example, having been alloted to physical and chemical equilibrium and to the Nernst theorem

The section on the classical theory of radiation, again, is not developed with the rigour of M Planck's "Wärmestrahlung," the conception of rays being made more use of than that of cones of radiation, but there are complete proofs of the laws of Kirchhoff, Stefan, and Wien, the last being obtained by the help of Westphal's geometrical simplifications A derivation is also given of the formula for the number of independent vibrations of a continuous medium, whilst there is a chapter on power cycles, and one on the equation of state of solids, the latter being a good introduction to the work of Born, Debye, and Lennard-Jones in this field An appendix includes a short but useful list of thermodynamic relations, and a few pages on the properties of steam

It must be emphasised that this is essentially a text book, and that it is not intended for specialists It should, nevertheless, interest many who have left the days of examinations far behind them, and its value for these readers will be enhanced by the numerous foot note references to original papers With regard to its chief aim, it is very difficult to predict with any certainty whether or not any text book will appeal to students The writer has, however, already brought it to the notice of his classes, and so far as can be judged from the short time during which it has been in use, it fulfils its purpose admirably, there is every indication that Dr Roberts will have to be congratulated on having produced a book that can be recommended for examination purposes without an alternative

K G E.

British Ferro-Concrete Bridges

Reinforced Concrete Bridges the Practical Design of Modern Reinforced Concrete Bridges, including Notes on Temperature and Shrinkage Effects By W L Scott, assisted by C W J Spicer Second edition, enlarged Pp xii + 220 + 26 plates (London Crosby Lockwood and Son, 1928) 25s net

DURING the past decade a very great extension in the use and art of reinforced concrete construction has taken place Particularly is this the case in connexion with bridges, and the considerable number of important bridge structures of ferro concrete erected in Great Britain within recent years is significant of the activity of development Generally speaking, the employment of such forms was noticeable at an earlier date both in America and on the Continent, and the foreign literature on the subject is fairly extensive But the book before us probably represents the only volume published in Britain wholly devoted to the exposition of bridge design and construction in reinforced concrete As such it is both necessary and welcome

Reinforced concrete design developed along rather crude empirical lines at first, and under such conditions bridge construction in this material was somewhat tentative and not free from fears as to reliability Paradoxically, the destruction of bridges during the War provides the best proof of the inherent powers of resistance of this class of construction when well designed and soundly built, the difficulty of completely destroying them having been well demonstrated In first cost, probably the reinforced concrete bridge does not offer any great advantage over the steel structure, but in upkeep charges it is superior The present volume does not deal with costs, but it displays considerable power in the art of straightforward exposition of forms and design methods and it covers the range of suitable concrete bridge types very clearly

After chapters on rolling loads and influence lines, wind pressure and temperature effects, etc, which may be considered preliminary to the main theme, the author proceeds to discuss arch bridges and the elements of their design in detail The ferro-concrete type lends itself to the arch form of construction most appropriately, and has, indeed, been the chief cause of a considerable development in the theoretical bases of rigid arch design The book deals with both hinged and hingeless arches, but in the main the details of analysis are limited to the parabolic forms of these The author presumably considers the development adequate to cover the variations therefrom

A clear chapter is given on girder bridges and includes consideration of both the parapet girder and the deck slab and beam types. This is followed by a short chapter on the bowstring girder, which, as it has developed in reinforced concrete work, becomes a variant of the arch type, in which is incorporated a horizontal member suspended directly from the rib. The weakness, in reinforced concrete, of the diagonal shear members common in steel girders, is explained.

The remaining part of the book discusses temporary and permanent hinge construction and deals with the problems of foundations and abutments. The last chapter gives brief explanatory descriptions of several characteristic and important constructions. This includes an outline of the difficult and unique Oswald Street Bridge at Glasgow; but does not refer to the Royal Tweed Bridge at Berwick, the main span of which is the largest reinforced concrete span yet erected in Great Britain. There is an appendix dealing with specifications and materials. The diagrams throughout the book are noticeable for simplicity and clearness; while the many excellent photographs of bridges throughout the text and in the last chapter convey a very clear impression of the artistic effects achieved in modern reinforced concrete bridge design.

A New Spider Book

The Biology of Spiders. By Theodore H. Savory. (A Series of Biological Handbooks.) Pp. xx + 376 + 16 plates. (London: Sidgwick and Jackson, Ltd., 1928.) 16s. net.

MR. SAVORY has performed a useful task in collecting together into one volume the main facts of the biology of spiders. The ideal suggested in the preface, that the reader should have no need to look elsewhere for further information on the subject, was, of course, a counsel of perfection, but for most purposes the account is adequate. The student intending to embark on research—on eye structure, for example—will certainly not be content with the sketch here presented, but he will be greatly helped by an excellent bibliography, very conveniently arranged under appropriate headings.

About the section on external and internal structure little need be said. Mr. Savory is a competent zoologist in addition to being a very keen student of spiders, and his summary of morphological facts may be trusted, and will be found sufficiently complete. The illustrative figures are diagrammatic but generally to the point, though we are rather surprised that he should have passed Fig. 37 (p. 54); this is decidedly misleading as regards the œsophagus, which would appear to have no communication with the outside world. We turn with more interest to the subsequent bionomic sections, which the author justly claims to contain certain original contributions to what would otherwise be a mere compilation—useful though such a compilation might very well be.

The chapter on behaviour is interesting, and we commend the author's insistence at the outset on a cautious interpretation of the phenomena observed. The commonest mistake of naturalists is the attribution to the creatures they study of mental powers which they are far from possessing, and we are inclined to agree with Mr. Savory when, on a later page, he suggests that even such practised observers as Bristowe and Locket have somewhat erred in this respect in their interpretation of the phenomena presented by mating spiders.

The chapter on the spider's web is brief, and is chiefly interesting for the author's views on the origin and evolution of the more complicated snares. These views are of course speculative, but they are at all events reasonable. Naturally he starts from what he calls "the drag line habit," which would necessarily result in the coating of the retreat. The spread of this coating to the immediate neighbourhood would give the sheet web of *Tegenaria*, which Mr. Savory regards as the primitive type of snare, and the other forms appear to him to have arisen from the need to economise in silk.

Mr. Savory's account of protective coloration and mimicry gives, in a small space, all the important facts, and his acquaintance with current literature is shown by the inclusion of the interesting experiments of Gabritschevsky on changes of colour exhibited by *Misumena vatia*, published in 1927.

In dealing with mating habits, Mr. Savory of course alludes to the classic researches of the Peckhams on the antics of amorous jumping spiders, but he is chiefly concerned with the more recent observations of Gerhardt, Bristowe and Locket on other araneid families. We regard his discussion of these phenomena as among the most interesting and valuable portions of the work.

After reviewing the fossil spiders and the trap-door spiders, the author proceeds to consider the probable course of evolution of the whole order. He figures a hypothetical primitive spider and suggests lines of development resulting in the main divisions now recognised. A full discussion of his views would occupy more space than is at our dis-

posal Sufficient has been said to give a fair idea of the scope of the whole work

Mr Savory's style is clear, if his touch is not conspicuously light We rather regret his revival of the term 'spiderling' which used to irritate us in McCook, and we now and then find him employing an uncouth term What, for example, are 'Behaviourists'? The appendix on "Some other Arachnida" will be welcomed by certain of his readers, but we hope that when a new edition is called for, he will supply better figures to illustrate the ticks Those in the text are, not to put too fine a point upon it, atrocious C W

Birds of Malaya.

The Birds of the Malay Peninsula a General Account of the Birds inhabiting the Region from the Isthmus of Kra to Singapore with the Adjacent Islands By Herbert C Robinson (Issued by Authority of the Federated Malay States Government) Vol 2 *The Birds of the Hill Stations* Pp xii + 310 + 25 plates (London H F and G Witherby, 1928) 35s net

MR ROBINSON has produced his second volume on the birds of the Malay Peninsula with commendable speed, only one year having elapsed since the publication of the first volume, which contained the "Common Birds of the Malay Peninsula" The present contains descriptions of the "Birds of the Hill Stations," Mr Robinson having fixed a minimum level of 2500 feet for the purposes of his work

The title of the volume is perhaps a misnomer, for hill stations in the Malay States are still in their infancy, and the volume might have been called with greater accuracy "Birds of the Hill Ranges" The height of the majority of the main hill-ranges runs to some 7500 feet and, for the most part, they are covered with primitive forest but little cut up by villages and their cultivation, though intersected here and there by grassland and forest streams

In reviewing the first volume we have already expressed our regret that the author has been obliged to bring out his volumes in the form adopted The work has been divided into four parts In the first volume, as already mentioned, he dealt with the "Common Birds of the Malay Peninsula," whilst the two volumes still to come will include "Shore and Water Birds," the "Rarer Birds," etc Such a method of dealing with the avifauna of any country must necessitate an immense amount of unnecessary overlapping, which makes it very difficult for the would-be reader and student to find his way about in the different volumes In a vast area such as the Malay Peninsula, birds which are of great rarity in one part are common elsewhere, whilst many are restricted in their habitat to comparatively small areas and are absent elsewhere

In spite of this one great drawback, the present volume forms a most valuable, interesting, and well-written addition to our knowledge of the avifauna of the Malay Peninsula, and we congratulate its author on its production, which will fill a long-felt want The classification adopted is on the same lines as that for the past volume It commences with the game birds, continues with the pigeons, rails, raptores, and owls, and concludes with the Pico Passeres The author ignores orders and sub-orders and adopts the easier, and perhaps wiser, course of dividing his birds into families only On the other hand, he accepts a vast number of genera which are based on very slight characteristics Thus he resuscitates Hume's name *Athenoptera* for some of the Scops owls of the *spilocephalus* group, though these birds are almost indistinguishable from some members included by him in *Otus* In the circumstances it is perhaps discreet of the author not to attempt to explain to his readers the characters upon which he relies to distinguish his genera The 25 coloured plates by Gronvold are of their usual excellence and of a standard worthy of so important a work, the paper used for the text, however, is very heavy, and the large volume therefore somewhat inconvenient to handle

We are glad to see that Mr Robinson gives vernacular names to the great majority of forms with which he deals Many authors omit this important detail on the grounds that trivial names given by Orientals are of no value, as they refer only to classes and not to species of birds Most of them forget that these class names are nearly always amplified by prefixes descriptive of the particular species described

We shall look forward with pleasure to Mr Robinson's future volumes, which we feel sure will be of equal value to the present

Physics for Non-Specialist Students

Physics for College Students an Introduction to the Study of the Physical Sciences By Prof A A Knowlton Pp xix + 641 (New York McGraw-Hill Book Co, Inc, London McGraw-Hill Publishing Co, Ltd, 1928) 18s 9d net

PROF KNOWLTON'S text-book is an attempt to treat the subject matter of physics in such a way as to justify its study by students who do not

need it for future technical work but simply for its general educational value Having taught physics for twelve years in an engineering college where it required no justification, the author moved to an arts college and was then faced with the question Why should students study physics ? This book is an outcome of his attempts to present the efforts of man to systematise and master his physical environment, in such a way that the question is satisfactorily answered In order to do this, he has had, inevitably, to drop the usual more or less logical presentation of physics under separate headings of mechanics, heat, etc , and further, to add the necessary spice, he has included a good deal more of the 'new physics' than is the custom in such text books This entails leaving out certain portions, chiefly accounts of the older classical experiments, and methods of measurement, the latter being left to the laboratory course the book is thus kept a reasonable size , there are fifty chapters, each meant to be read comfortably at one sitting

The first chapter explains the place of physical science in modern civilisation and gives an excellent account of scientific method and attitude of mind and the distinction between facts and hypotheses Starting from the notion of 'work,' since "work is the most general and important article of commerce in the modern world," the author leads up to the concept of 'energy,' which is the central theme of the book This accounts for the early introduction of chapters on the measurement of energy in its various forms and on the connexion between matter and energy In the thirteenth chapter the sun is considered, as an introduction to the study of the sources and modes of distribution of energy, and this leads to the treatment of the motion of falling bodies, the production of motion, spectra, magnetic and electric fields, and atomic structure Then after wave motion comes radiation, leading up to X rays, relativity, and quantum theory The remaining fourteen chapters deal with the physics of the air, including sound, properties of matter, solid and fluid, some simple thermodynamics, and, finally, some more advanced magnetism and electricity with their practical applications

The obvious advantages of this method of presenting a subject like physics are that it enables students, after the first few chapters, to have a mental background against which further knowledge can be viewed, and it also allows what Prof Knowlton calls a cyclic arrangement, that is, a constant reiteration of fundamental facts and principles The attempt made throughout to utilise, in explanation, things familiar in everyday life is specially noticeable in the list of examples which follow each chapter, which are graded as to difficulty In fact, some of the problems are so attractive as to be almost irresistible, which is saying a good deal There are also timely paragraphs on scientific accuracy, measurement of quantities which vary irregularly, physical 'laws,' etc , and nowhere has true scientific caution been sacrificed to enthusiastic stimulation of interest The illustrations are good, especially the photographs in the optical section

Prof Knowlton has certainly succeeded in producing a text book which justifies its own study , and it is with no surprise that one learns that it has already met with "marked student approval"

Zoology for Indian Students

An Elementary Text Book of Zoology for Indian Students Adapted from "An Elementary Course of Practical Zoology," by Profs T J Parker and W N Parker Second edition By B L Bhatia Pp xii + 684 (London Macmillan and Co , Ltd , 1928) 15*s* net

SOME nine years ago the excellent "Elementary Course of Practical Zoology, by T J and W N Parker, was taken in hand by Mr B L Bhatia, of the Government College, Lahore, and adapted to the special needs of Indian students The book in its new form, entitled "An Elementary Text Book of Zoology for Indian Students," has now deservedly reached a second edition While the plan follows in general that of the Parkers' original book, it has been modified so as to make it less of a mere description of 'types' and more of a general text book

Part I , occupying about a third of the volume, remains as before—a description of the frog, forming an admirable introduction to vertebrate anatomy, histology, and physiology There are various improvements in detail, as, for example, in the figure of the frog's heart, which is still capable of improvement, as is also the account of the physiological action of the conus arteriosus

Part II shows more alteration A good account of the malarial parasite is given , the student is told how the mosquito "not only sucks blood but also spits into the wound," and his attention is further gripped by his being made to realise how India was the scene of Ross's original discoveries, and how practically important to India is the successful prevention of malarial disease

In the list of special types, various changes have been made to suit Indian conditions The earthworm is no longer the familiar *Lumbricus*, but the

Indian *Pheretima posthuma*, which, while in many respects equally suitable, suffers under the great disadvantage from the teacher's point of view that its nephridial organs are of extreme complexity and accordingly much less suitable than those of *Lumbricus* for driving home certain of the important general principles of the morphology and physiology of renal organs The crayfish of the Parkers' book is replaced by the prawn *Palæmon*, so far as external features are concerned, and the cockroach , while, as is entirely suitable, a short sketch is given of the life history of a mosquito The freshwater mussel as a type has been cut out, while on the other hand there have been added to the book chapters dealing with more general aspects of zoology The main groups of the animal kingdom are briefly reviewed, and the volume concludes with three chapters dealing with cytology, embryology, and evolution

Here and there are details which should be looked into when the next edition is being prepared—such as the references to 'true bone,' air bladder, and conus arteriosus of fish , and the absence of nephrostomes in the metanephros In the chapter on evolution there is still apparent the tendency to think in terms of organs or parts of organs instead of in terms of individual animals , while many teachers would regard it as an improvement to drop entirely the terms 'acquired character' and 'mutation'—the first because its use seems at once to cause confusion of thought in certain minds, the second because its use by different writers in different senses has caused it to lose its value as a precise scientific term

Apart from such minor blemishes in detail, the book is a thoroughly good one and may be warmly recommended to Indian teachers and students of zoology It is well illustrated, and the descriptions of the various animal types are accompanied by excellent directions for their practical investigation by the student

---

A Bibliography of Bibliographies

Bibliography—Practical, Enumerative, Historical an Introductory Manual By Henry Bartlett Van Hoesen, with the collaboration of Frank Keller Walter Pp xv + 519 (New York and London Charles Scribner's Sons, 1928) *27s 6d* net

THIS work is based upon a series of lectures delivered annually at Princeton University since 1923 Its principal object is to train the graduate student in the use of bibliographies, and to inculcate the value of method in his practice The backbone of the work is a bibliographical appendix covering some eighty pages and enumerating more than two thousand bibliographies, and the first eleven chapters of this work are in the nature of a commentary upon the bibliographies listed

The authors rightly stress the fact that their manual is introductory rather than complete, and that their aim has been to set the student's feet on the right path of investigation rather than to load him with descriptions of all necessary material Within these limits we consider that the work has been carried out successfully The selection of bibliographies is judicious and singularly free from national bias, and the critical commentary proves that the authors are skilled craftsmen Omissions, of course, there are Archive searching should have been given a separate chapter, and the "Official Guide to the Public Record Office of Great Britain" should have been included Under 'technology,' again, we find an entry for the 'Catalogue of the German Patent Office," but none for that of the British Patent Office, or for its numerous 'Guides" and 'Subject Lists" A more serious defect is the weakness of Chapter ii on practical bibliography The nature of research is insufficiently explained, and the collection of bibliographical material and the rules for compiling bibliographies are treated together although the two subjects are entirely distinct Most collectors err on the side of false economy and pay for it in after life by having to recopy or remount their collections on paper of larger size The modern 'ringbooks' appear to offer one satisfactory solution of the problem

Again, the student should be warned against undertaking work for which he lacks the necessary technical equipment An engineering subject demands an engineering training Jenkins's 'Power Locomotion on the Highway," 1896, and Hopwood's "Living Pictures," 1899, are fair examples of successful bibliographical work by competent men The bibliographer should also be advised that, in whatever order he elects to publish his bibliography, he should at some period of its compilation sort his entries in chronological order and submit them afresh to critical examination , for chronological order solves many questions of authorship, priority of statement, and other bibliographical problems We think that in this chapter the authors have leaned too heavily upon outside opinions, which are often contradictory and far from helpful

The final chapters of this work are careful compilations of the histories of writing, printing, and book production They form interesting reading, but add little to the practical value of the work

Our Bookshelf

Archæology

Oraon Religion and Customs By Rai Bahadur Sarat Chandra Roy Pp xv + 418 + 20 plates (Ranchi *Man in India* Office, 1928) 12 rupees

ETHNOLOGISTS are indebted to Sarat Chandra Roy for his valuable book "The Oraons of Chota Nagpur" (1915), and now he has provided a study of Oraon religion and customs which should be read by all those who are interested in primitive religions The Oraons (or Kurukhs) are immigrants on to the plateau which they share with the aboriginal Mundas and other tribes

The especial value of this book is not merely in the detailed accounts of socio religious and religious rites and ceremonies and magical practices, but in the very suggestive religious transformations that have occurred since the Oraons arrived, and the process is still continuing The original religion centred round (1) the supreme spirit, or spirit of good, Dharmes, who was formerly the sun lord, the author, preserver, controller, and punisher of men, gods, and spirits, and (2) the 'evil eye' and 'evil mouth' as representing the spirit of evil Most of the village gods and spirits were appropriately borrowed from the Mundas, who had long been settled on the land, and a few have been borrowed from their Hindu neighbours There are also ancestor spirits whom the deceased Oraon joins on the annual 'great marriage' or 'bone drowning' day, apparently these were formerly considered to be mischievous, but now are mainly beneficent The most important annual ceremony is the spring festival of the 'marriage' of the village priest with his wife, in token of the marriage of the sun god with the earth goddess, so that the earth may fructify, probably it is a survival of a festival of the food gathering stage in their history The licentiousness permitted on this occasion is believed to stimulate the fertility of the earth

The germ of the Bhakti cults was very ancient, but under Hindu influence it was fructified as reverent faith in and loving adoration of a personal deity, thus was the way prepared for Christianity, which was introduced in 1845 Hindu organisations have tried to bring the Oraons into the official Hindu fold by giving them ceremonial purification, but with little effect

Chivalry a Series of Studies to illustrate its Historical Significance and Civilising Influence By Members of King's College, London Edited by Prof Edgar Prestage (The History of Civilisation Series) Pp xv + 231 + 24 plates (London Kegan Paul and Co, Ltd, New York Alfred A Knopf, 1928) 15s net

A VOLUME composed of a series of lectures delivered by a number of individuals must necessarily lack the unity of outlook of a book by a single author This is a serious defect in dealing with so important a factor in the history of western civilisation as chivalry However great an authority each of the authors whose lectures are included here may be on his special branch of the subject, the description of the characteristics of chivalry of countries—England, France, Spain, Portugal, and so on—misses the interpretation of the facts which is the function of a history of culture such as this series aims to be Hence apparent discrepancies in the attribution of chivalry as a characteristic outcome of the temperament of now one, now another, nation

A broader treatment would have brought out the fact that chivalry was an expression of the ideals, temperament, and culture of the Nordic peoples who had imposed themselves as rulers over a great part of Europe Hence the paradox of chivalry that its ideals prevailed within the caste only, and did not affect relations with the community, who, in fact, were a subject population Subject to this reservation, this book is an addition to the literature of chivalry which is to be valued, especially where it breaks new ground The illustrations, as nearly as possible contemporary, have been particularly well selected

The Ancient Wells, Springs, and Holy Wells of Gloucestershire their Legends, History, and Topography By R C Skyring Walters, Pp xiv + 194 + 62 plates (Bristol The St Stephen's Press, 1928) 12s 6d

GLOUCESTERSHIRE, owing to its geological formation, is a county exceptionally rich in springs and wells The remote character of much of its country side has tended to preserve the memory of the sacred character attributed to water by early man, which in modern times survives in the association of the well with a Christian saint In his descriptive account of the numerous sacred wells of Gloucestershire, Mr Walters, while constantly recognising that paganism lies at the root of the esteem in which the wells have been held, does not as a rule offer any suggestion as to the origin of the specific cults, or trace it further back than the dedicatory saint The custom of offering pins, rags, and coins to the well he attributes to the Romans, but the distribution of the custom in Great Britain and its prevalence in Ireland point to a more remote origin Mr Walters admits Wandswell as "at least one survival of paganism," the name being connected with Woden, but to speak of "Christian well worship" is a contradiction in terms unless Christian is used merely in a chronological sense

The Vampire his Kith and Kin By Montague Summers Pp xv + 356 + 8 plates (London Kegan Paul and Co, Ltd, 1928) 15s net

LIKE his books on witchcraft, Dr Summers' study of the vampire combines a vast erudition with a complete acceptance of the orthodox theological point of view Some knowledge of the history of

controversy relating to witchcraft and demonology is requisite in order that the reader may not dismiss the book as merely credulous and not, as it is, a real contribution to the literature of the subject Yet it may not be uninstructive to mention one minor matter which brings out clearly the author s point of view He accepts the real existence of the vampire That is a matter of authority He doubts that a nurse was in attendance when Bram Stoker s play ' Dracula " was presented in London Yet this was a statement of fact and could have been verified by inquiry If however the reader is prepared not to exact a scientific spirit of scepticism, Dr Summers' book will be found a mine of information relating not only to the vampire belief but also to the abnormal pathological states which without doubt gave rise to the belief—a gruesome but nevertheless instructive field of inquiry

Biology

Faune de France 18 *Diptères* (*Nématocères*) *Chironomidæ* III *Chironomarıæ* Par M Gœtghebuer Pp 174 32 francs 19 *Hyménoptères vespiformes*, II (*Eumenidæ*, *Vespidæ*, *Masaridæ*, *Bethylidæ*, *Dryinidæ*, *Embolemidæ*) Par L Berland Pp viii + 208 (Fédération française des Sociétés de Sciences naturelles Office central de Faunistique) (Paris Paul Lechevalier, 1928) 36 francs

The Faune de France ' series of monographs is now familiar to most zoologists and the separate parts already issued have been noticed at intervals in our columns The two most recent fascicules that have come to hand form Nos 18 and 19 in that series , No 18, by M M Gœtghebuer, is concerned with midges forming the tribe Chironomariæ of the family Chironomidæ, and No 19, by M L Berland, deals with the true wasps, together with certain related groups commonly united to form the family Bethylidæ The method of arrangement adopted in these two parts is similar to their predecessors , namely, a short introduction on structure and biology followed by generic keys under each genus is a key to the species, while each species is separately described, its general distribution indicated, and any important facts known relative to its biology are recorded The numerous illustrations and full bibliographic references are also noteworthy We commend these two monographs to the notice of English entomologists, since the French fauna includes most of the British species in the groups concerned A D I

Gilbert White Pioneer, Poet, and Stylist By Walter Johnson Pp xvi + 340 + 4 plates (London John Murray, 1928) 15s net

Many commentaries on the writings of Gilbert White have been published, but none has worked out in such detail the aspects seized upon in this volume In analysing the matter and the method of presentation of White s observations, the author has naturally lost the very essence of the attractiveness of the original works, but he has made a scientific appreciation which will be valued by those who would understand the place of these observations in the light of modern knowledge

The disconnected studies of " Selborne " and other works are here grouped and classified in their due relationship, ecology, birds, other vertebrates, insects, botany, geology, meteorology, and the like, and there are excellent chapters on the man, the scope of his work and the distinctive quality of his prose style Throughout the work the reader is brought in close touch with the meticulous observation glimpses of far seeing speculation, simple and clean cut phraseology, which have made ' Selborne the most widely read of Nature books The author claims that all the information of scientific value not previously printed from White's MS has now been transcribed and made public in this volume

Organographie der Pflanzen insbesondere der Archegoniaten und Samenpflanzen Von Prof Dr K von Goebel Teil 1 *Allgemeine Organographie* Dritte umgearbeitete Auflage Pp ix + 642 (Jena Gustav Fischer 1928) 30 gold marks

This new edition of the general section of a well known text book has increased considerably in size and the new material has not been simply interpolated, but the balance of the book has gradually changed with the maturing views of its veteran author as whole sections have been rewritten and reduced or increased in prominence The tendency seems still to be towards a stressing of the interrelationship of environment and organism during development This side of organ development receives much attention in the general introduction, and is the special subject of the last ninety pages The book remains an invaluable mine of information, especially upon experimental morphology The illustrations in the new edition have increased in number from 459 to 621, most of them the work of the author, his colleagues and students

Chemistry

Symbols and Formulæ in Chemistry an Historical Study By Prof R M Caven and Dr J A Cranston (Manuals of Pure and Applied Chemistry) Pp ix + 220 (London, Glasgow and Bombay Blackie and Son, Ltd , 1928) 15s net

Symbols and formulæ have been used incessantly from the early days of alchemy down to these modern times in which a radiating atom of sodium is represented by the scheme $^2S_{\frac{1}{2}} - {^2P_{\frac{1}{2}}}$ The title selected by the authors therefore provides them with a convenient excuse for drilling a bore hole through the whole of the strata in which the history of chemical theory is embedded The samples which they have extracted are naturally not the same as if they had been concerned with the general history of chemistry, and many obscure details are brought into the light of day , but the reader will find that the atomic and molecular theories the earlier and later theories of molecular structure, including stereochemistry and co ordination, fall

within the scope of the volume, as well as the modern electronic theory

The reader has thus an opportunity of taking an unfamiliar course through familiar fields of study, and will be well repaid for doing so It is a pity, however, that the cost of this sectional history is greater than that of a more comprehensive text book, since many readers who would purchase the latter will be content merely to borrow the former

T M L

Fixation of Atmospheric Nitrogen By Frank A Ernst (Industrial Chemical Monographs) Pp ix + 154 (London Chapman and Hall, Ltd , 1928) 12*s* 6*d* net

THE author of this book points out in the preface that it is not written for the scientific specialist, but "for the teacher and student, for the business man and banker " The book deals first with the sources of nitrogen and the need for its fixation from the atmosphere, and then considers in detail the arc process, the cyanamide process, the direct synthetic ammonia process, and ammonia conversion products The material is well presented, and is especially valuable on account of the full statistics given not only throughout the text and the chapter entitled "Statistics," but also in the tables at the end of the book A fair bibliography is also included The chapter dealing with ' Economic Considerations " indicates clearly a number of economic problems that arise in the commercial fixation of nitrogen At the beginning of Chapter ii (p 11) Bertholet is mentioned instead of Berthollet, and Sir Humphry Davy's name is spelt incorrectly No mention is made of MacDougall and Howles, who first worked the arc process in Manchester, and whose patent (1899) preceded that of Bradley and Lovejoy (1902), on the basis of which the author (p 12) claims that "the industrial fixation of nitrogen thus had its birth in the United States "

The Problem of Fermentation the Facts and Hypotheses By M Schoen With an Introduction by Prof A Fernbach A Monograph of the Institut Pasteur, translated from the French by H Lloyd Hind, and revised and enlarged by the Author Pp xii + 211 (London Chapman and Hall, Ltd , 1928) 21*s* net

THE author gives an interesting account of the present position of the problem of fermentation and traces its development from the time of Pasteur to the present day The whole range of the subject is covered alcoholic and lactic acid fermentation, the place of pyruvic acid and acetaldehyde in alcoholic fermentation, the function of phosphates and the effects of changing the reaction of the medium Analogous processes in animal tissues are frequently referred to, such as the function of lactic acid in muscular contraction or in malignant growths The references are given at the foot of each page and are also collected into a bibliography of some forty pages, which in addition serves as an index of authors' names This is a volume for the specialist, but should be widely read also by those interested in related subjects for the light it frequently sheds on processes which bear some analogy to alcoholic fermentation itself

The Determination of Hydrogen Ions an Elementary Treatise on Electrode, Indicator, and Supplementary Methods, with an Indexed Bibliography on Applications By Prof W Mansfield Clark Third edition Pp xvi + 717 (London Baillière, Tindall and Cox, 1928) 30*s* net

PROF CLARK'S standard work on the determination of hydrogen ions is too well known to require any introduction The third edition, recently issued, has been thoroughly revised and brought up to date The author points out that the number of papers on this subject has rapidly increased in recent years, so that, in spite of revision and enlargement, the work probably covers the field less completely than the first edition In spite of this, few except the advanced specialist will fail to find details required within its pages on the colorimetric or electrode methods of determination The subject is treated from both the practical and theoretical points of view, and forms a very complete treatise As the question of hydrogen ion activity enters into most biochemical problems to day, selected portions of the book will be of value to most biochemists and physiologists, and can be studied with profit There is an extensive bibliography and a list of definitions of common terms

Scent and All About It a Popular Account of the Science and Art of Perfumery By H Stanley Redgrove Pp viii + 100 (London William Heinemann (Medical Books), Ltd , 1928) 3*s* 6*d* net

THE careful reader of Mr Redgrove's booklet will gather many unusual items of information, such as the natural sources of ambergris, frankincense, opoponax (a name for perfumers to conjure with "), and civet He will notice that the civet used in Great Britain comes mainly from Abyssinia, packed in ox horns , that the odour of Jockey Club is that of the sweet wild flowers wafted over Epsom Downs , that diphenyl oxide develops an odour of geranium leaves only in dilute solution , that labdanum, the nearest approach to ambergris in the plant world, is gathered by shepherds from the fleeces of sheep which browse on the hills of Cyprus and Crete , and that the garden musk (*Mimulus moschatus*) of the present day has lost its odour, possibly owing to the fragrant plant of our ancestors having been a ' form ' which has since died out Within its modest limits this little book amply fulfils the author's purpose of providing the general reader with a popular account of the science and art of perfumery

J R

Inorganic Chemistry Vol 1 *Non Metals* By Dr G H Bailey and Dr D R Snellgrove Pp viii + 488 (London University Tutorial Press, Ltd , 1928) 6*s* 6*d*

THIS book, together with the companion volume, "Inorganic Chemistry Vol 2 Mainly Metals," is intended to cover the course for an intermediate

university examination, and is well produced for its price The style is clear and interesting, but a lack of original and more inspiring illustrations does not aid its favourable comparison with some other recent text books of similar character The statement is made on p 198 that the absorption of bromine vapour by iron filings produces ferrous bromide, $FeBr_2$, the compound formed is Fe_3Br_8, and is an important source of potassium bromide The paragraph on sulphur heptoxide, S_2O_7 (p 347), gives the impression that no further work has been carried out since Berthelot's supposed discovery in 1877

An Introduction to the Chemistry of Plant Products By Dr Paul Haas and Dr T G Hill Vol 1 *On the Nature and Significance of the Commoner Organic Compounds of Plants* Fourth edition Pp xvi + 530 (London, New York and Toronto Longmans, Green and Co , Ltd , 1928) 18*s* net

NOTWITHSTANDING the systematised courses in biochemistry which are now available in many centres, the new edition of this book will continue to subserve the authors' original aim of providing students of biology with an account of the chemistry and physiological significance of some of the more important substances occurring in the plant It contains sections on fats, oils, and waxes, aldehydes and alcohols, carbohydrates, glucosides, tannins, pigments, nitrogen bases, the colloidal state, proteins, and enzymes , there is also an appendix on hydrogen ion concentration It has been brought up to date, and although necessarily it contains a good deal of somewhat elementary matter, one may suggest that it could be read with profit by organic chemists who are wishful to view their subject from a biological outlook J R

Engineering

Foundations the Examination and Testing of the Ground preliminary to the Construction of Works—Methods and Appliances By William Simpson (The Glasgow Text books of Civil Engineering) Pp xviii + 256 (London Constable and Co , Ltd , 1928) 18*s* net

THIS book is the latest addition to the well known series of civil engineering text books produced under the general editorship of Prof Moncur, of the Royal Technical College, Glasgow Its scope is well indicated by the sub title It is wholly concerned with the study of the ground and of those methods of examination and test to be followed in the collection of essential data on which to base the design of the foundation arrangements for heavy structural work The first chapters deal with the features of geological surveys, and, indeed, the whole book gives a very clear impression of what the author refers to as "the intimate relationship which exists between Structural Geology and Civil Engineering" The development of the subject proceeds through a very complete discussion of boring and test shaft methods under all conditions, both on land and under water The final section provides a clear treatment of the procedure and appliances necessary for testing the bearing capacity of the ground by direct loading on open areas, and by test pile or exploratory tube methods in deep foundations

The book throughout is concerned with the practical problems, apparatus and operations of search There is no collection or classification of specific ground data but the care with which the detail appliances and methods are explained, the descriptive excellence of the text and the clearness of the diagrams, combine to make the book eminently suitable for students

Television By Alfred Dinsdale Second edition Pp xx + 180 + 33 plates (London Television Press, Ltd , 1928) 5*s* net

IN a foreword to this little book, Dr J A Fleming recommends it to those who desire an all round view of the art of television as it exists at present, and of the problems and difficulties which still face the inventors in this novel field of adventure We entirely agree with him He also points out that in all inventions like the telephone, radio telegraphy, and television, there are two stages of development First of all an idea strikes some one , then various people try to realise it in practice The next stage is when an inventor like a Bell, a Marconi, or a Baird, makes an invention or discovers a device, sometimes very simple, which opens up a new pathway, and then progress is rapid When the right clue is obtained, success follows, provided financial aid is forthcoming and systematic experiments are undertaken The history of the past furnishes many similar cases

The reader, even although his knowledge of physics is limited, will have little difficulty in understanding this book There is a great demand by the public for anything new, for anything which contributes to the convenience of life, to entertainment, and to the dissemination of instruction and news The physical importance of the new discoveries and inventions is considerable, and unlike many theories they are built on a sound experimental basis The great obstacles to radio television to great distances at present are the disturbances caused by fading, Morse signals, atmospherics, and all the other causes which mutilate the broadcasting of speech and music

A Text Book of Telegraphy Theoretical and Practical By A E Stone Pp vii + 455 (London Macmillan and Co , Ltd , 1928) 20*s* net

THIS book can be recommended to the student who has some previous electrotechnical knowledge He will find that it is easy to understand The descriptions of the apparatus and the systems in practical use can be readily grasped as only essential parts are shown in the diagrams Special attention has rightly been given to multiplex systems and to type-printing telegraphs Only the most modern methods are described Alternating currents, the transmission of signals, submarine and radio telegraphy, are all touched on and the main theorems in connexion with them are given The mathematical proofs in several

cases are novel, and to be commended We were unable, however, to follow the proof of the self induction of two parallel wires forming a loop (p 82) However, the answer given is correct, which is the main thing from the practical man's point of view The distinctions between the capacity of a condenser, the capacity of a conductor, and the capacity between two parallel wires, are not clearly explained In proving the formula for the latter, the assumption is made that the charges can be concentrated along the inverse lines of the two cylinders A proof of this should have been given As a rule, the symbols have been happily chosen On p 47, however, Z is used to denote a current, this use we think quite inadmissible On p 402 it denotes impedance, a use which has international sanction

Geography and Travel

Antarctica a Treatise on the Southern Continent By J Gordon Hayes Pp xv + 448 + 16 plates (London The Richards Press, Ltd, 1928) 42*s*

THE knowledge of Antarctic matters has grown at so great a rate during the twentieth century, owing to the intensive scientific exploration of several areas, that a comprehensive work bringing together in one volume the results achieved cannot fail to be of value This is part of the task that Mr Gordon Hayes has set himself In addition, he gives a critical estimate of the value of recent expeditions, and attempts some forecast of profitable lines of discovery Beyond all this there are a number of appendices, a bibliography, many excellent illustrations, and a few maps

There can be no doubt that Mr Gordon Hayes has brought industry and enthusiasm to his task, and though he has no personal experience of polar work, he has at least the advantage of being an impartial critic of all expeditions Yet it must be admitted that the book has several omissions and not a few inaccuracies, and falls far short of being a treatise on Antarctica Some of his criticisms, such as of transport by man haulage, are of value, but his strictures of the Wilkes expedition are somewhat severe, and his basis for judging the success of an expedition by the length of coast line discovered is most unscientific His list of casualties, which he calls the Antarctic Roll of Honour, is incomplete

It is on the scientific side, however, as apart from the record of discovery, that the book falls far short of its author's aim This is not surprising when it is realised from the author's list of works consulted that his material is derived mainly from the popular narratives of expeditions These are not designed to give the scientific results They are for popular reading Of the many volumes of scientific reports of recent expeditions, practically the only ones mentioned are those of the *Terra Nova* and a few papers on the work of the *Endurance* Moreover, there is almost entire omission of French and German works even of a popular nature If Mr Gordon Hayes does not make use of the available sources of material, he cannot claim to have written an authoritative treatise

The People of Tibet By Sir Charles Bell Pp xix + 319 + 57 plates (Oxford Clarendon Press, London Oxford University Press, 1928) 21*s* net

SIR CHARLES BELL has written a most interesting and very well illustrated book on the mode of life and domestic customs of the Tibetans which may be accepted as authoritative The shepherds and herdsmen are probably the purest specimens of the race The inclement conditions, especially hailstorms, render the peasants' life a hard one There is a great gulf between these classes and the nobility the trading community forms a middle class, but with little power, the foreign trade is in their hands, and even the nobility have their commercial agents, for the Tibetan is a born trader Begging is a hereditary profession, but the monks who go a begging are on a different footing There are few countries where women have so good a position, and they are active and shrewd in business matters Monogamy, polygyny, and polyandry are all found in Tibet, but on the whole monogamy is more prevalent

The daily life of the gentry is permeated with ceremonial and etiquette, and the usages of courtesy in all its branches are carefully taught to the young Many of the troubles of travellers here and elsewhere have been due to non observance of etiquette Tibet does not lack land fit for cultivation, but lacks the men to till it The population is decreasing owing to various causes, perhaps more especially to the large number that live celibate lives in monasteries instead of rearing families

Geology and Mineralogy

Kohlenpetrographisches Praktikum Von Dr Erich Stach (Sammlung naturwissenschaftlicher Praktika, Band 14) Pp iv + 196 (Berlin Gebrüder Borntraeger, 1928) 10 80 gold marks

DURING the last twenty years great progress has been made in the study of coal Instead of treating it only as a material which on combustion gave certain products, investigators have been studying the material itself, its constituents, their mode of occurrence and association, and their probable method of origin Coal is a rock rather than a mineral, and much of the progress that has been made has come from its examination by petrological methods These methods have been developed independently in England, America, and Germany, and their results have been described in many widely scattered publications, consequently a brief summary of the work with a full list of references is very valuable

The present work is probably more valuable as a survey of the field than as a practical handbook In the preparation of coal specimens for microscopical examination there are so many technical difficulties and so many 'tricks of the trade' that it is doubtful whether anyone could be sure of success by simply following descriptions of the methods employed But after describing methods, the author gives a brief but impartial statement of some of the results achieved, illustrated with many

excellent photographs, and followed by a bibliography of nearly 300 titles The book can therefore be used as an introduction to the subject

The author differs from most British coal petrologists in recognising only three chief constituents in bituminous coal He considers that there is no fundamental difference between the clarain and vitrain of Stopes and other authors He seems to favour the view that the characteristic bodies in Boghead coals probably represent algal colonies

Some omissions were probably necessary in a work of this type, but we notice no reference to methods of bleaching or reducing the colour of coal sections The work of Lilpop (Cracow, 1917) on this subject is worthy of mention

The book should help students in the early stages of research work on coal, and we ought to have many more workers on this subject in England

H Hamshaw Thomas

Bau und Bewegung der Gebirge in Nordamerika, Skandinavien, und Mitteleuropa Forschungen in den Jahren 1924 bis 1927, ausgeführt mit Unterstützung der Notgemeinschaft der Deutschen Wissenschaft Von Hans Cloos (Fortschritte der Geologie und Paläontologie, herausgegeben von Prof Dr W Soergel, Band 7, Heft 21) Pp viii + 241 327 + 6 Tafeln (Berlin Gebrüder Borntraeger, 1928) 14 gold marks

Those interested in theories of crustal drift will find much to their taste in this small work Prof Cloos extends his conceptions of 'granite tectonics' to cover block faulting and the like His personal observations and remarks on the granite tectonics of the Sierra Nevada, on block faulting in Europe and America, and on the structure of the Western States, are of permanent value, whatever may be the fate of his deductions from them

The theory advanced is that certain tectonics of the crust result from a world wide northward flow of subcrustal material against obstacles One expression of this appears in the wedge-form of the continents arising, as it were, from erosion by such a current Again, the structure of western America is explained by a south to north Pacific stream impinging on the continental margin Part of this stream is deflected to the north west, part passes beneath the continent, and both give rise to correlated tectonic effects Geologists who favour Wegener's continental drift theory would do well to compare it with these speculations of Cloos To one not particularly attracted by either hypothesis, the continents appear to be becoming embarrassingly mobile

The printing is excellent and the plates good, especially one showing the fault-plane of the Christiania trough

The Nomenclature of Petrology with References to Selected Literature By Prof Arthur Holmes Second edition Pp v + 284 (London Thomas Murby and Co , 1928) 7*s* 6*d* net

The second edition of Prof Holmes's extremely useful "Nomenclature of Petrology" is chiefly notable on account of its reduction in price from 12*s* 6*d* to 7*s* 6*d* This no doubt will be welcomed by students and research workers, who will find the volume a comprehensive and handy work of reference

While the author has made a few corrections and slight modifications, there still remain a few inaccuracies, and one still looks in vain for one or two well established terms During the eight years that have elapsed since the first edition, many new words have been introduced into petrological nomenclature The author points out that these are, for the most part, of minor importance Nevertheless, for this reason their usage is likely to be unfamiliar It is therefore regrettable that, on the score of the expense, it has not been found possible to incorporate them in the new edition The deficiencies of the book are trifling, however, and do not appreciably detract from its general utility

Medicine

The Blood Plasma in Health and Disease By Dr J W Pickering (Monographs on Medical and Surgical Science) Pp xi + 247 (London William Heinemann (Medical Books), Ltd , 1928) 12*s* 6*d* net

The author has performed a useful service in collecting within the pages of a single volume what is known about blood plasma as distinct from the formed elements of the blood Much has been written about the physiology and pathology of the different blood corpuscles, but the results of work on the plasma have heretofore remained scattered and uncorrelated In brief, this book treats of the composition of the plasma proteins and their relationship to each other, and of blood coagulation, the physiology of the process and how it can be aided or retarded, with the known pathological alterations in its mechanism

Upwards of 900 papers are referred to, and it is probably the brief accounts of these investigators' researches following each other in succession from page to page which makes the book rather difficult to read This is not to say that the author does not attempt to summarise the work quoted and to indicate what in his opinion is the most probable conclusion Thus the author's view of the process of blood coagulation may be briefly stated as follows Part of the prothrombin of the plasma is loosely bound, but the greater part is firmly bound, the various proteins being looked upon as a colloidal co ordinated complex rather than as separate fractions independent of each other The loosely bound prothrombin unites with protein-phospholipin (cephalin) complexes from disintegrated platelets, to form thrombin, which rapidly unites with fibrinogen, releasing the firmly bound prothrombin, to react further with cephalin He also considers that there are at least three methods by which plasma can be converted from a sol to a gel, and that it is a mistake to assume that one single process is always responsible for the formation of the fibrin clot

The theoretical aspects of the subject are made the basis of correlating our knowledge of the

pathology and treatment of abnormal bleeding, and a useful appendix is given of the composition and actions of, and indications for, a variety of commonly used hæmostatics The work will be of interest both to physiologists and clinicians, and further volumes in this series of monographs will be welcomed

On Rous, Leucotic, and Allied Tumours in the Fowl a Study in Malignancy By Dr J P McGowan Pp vii + 99 + 11 plates (London H K Lewis and Co, Ltd, 1928) 10s net

THE observations recorded by Dr McGowan in this book are a sequel to his study of pernicious anæmia and allied blood diseases, in the course of which he investigated leucosis of fowls and noted sporadic cases of sarcomatous tumour A detailed examination of these tumours and of the Rous sarcoma No 1 now lead up to a study of the etiology of malignant growths, with the conclusion that sarcomatous tumours of fowls, including those of a leucotic nature, are probably caused by various non-specific irritants Evidence is produced to support the thesis that these tumours are manifestations of disease of the hæmatopoietic tissues, the pathology of which is discussed in considerable detail

Whether the evidence justifies the author's conclusions must remain at present a matter for individual opinion, but whatever this may be, it will be agreed that careful research such as Dr McGowan describes cannot but assist in elucidating the problems of malignancy

Metallurgy

Impurities in Metals their Influence on Structure and Properties By Dr Colin J Smithells Pp xi + 157 + 23 plates (London Chapman and Hall, Ltd, 1928) 18s net

EXACT knowledge of the effects of impurities on the properties of metals is of fundamental importance to the metallurgist and engineer as well as to the physicist or chemist who uses metals as the subject of his researches There is, therefore, ample justification for the publication of a volume treating specifically this aspect of metallurgy Until the author took the subject in hand, no such book had been produced, but whether the present treatise is the one for which metallurgists have been unconsciously looking is quite another matter The author himself states that he would have preferred to use the term 'minor constituent' instead of impurity, and it is certainly very difficult to justify the application of the word 'impurity' to, for example, the large amount of chromium deliberately added to the stainless steels, to which addition in fact these materials owe entirely their characteristic properties

The effects of impurities on the mechanical properties of metals are quite inadequately treated Industrially, the most important metallurgical impurities are probably sulphur and phosphorus in iron and steel Of these, the former is dismissed in a few lines, and the latter scarcely mentioned From the historical point of view, too, one would have expected at least a brief reference to the pioneer researches of Roberts Austen and Arnold and Jefferson on the effects of impurities on copper and gold None of these workers is even mentioned

Although much interesting and useful information is made available in a handy form, the work leaves one with the impression that the range of the author's knowledge is too circumscribed to fit him for the task which he has undertaken The book as a whole is disappointing, and the subject still deserves and needs a far more complete and balanced treatment It is to the author's credit, however, that he had made us aware of the real need for a book treating as a whole the subject, some parts of which he has himself considered

Cast Iron in the Light of Recent Research By W H Hatfield Third edition, revised and enlarged Pp xv + 340 (London Charles Griffin and Co, Ltd, 1928) 16s net

IN spite of the extensive use of cast iron as a structural material, its scientific study has lagged conspicuously behind that of steel Until quite recently, the knowledge of its constitution has been almost entirely empirical, and success in its use has been due to the practical skill of foundrymen rather than to an understanding of the factors which determine its constitution Since the first edition of Dr Hatfield's book was published, there have been determined efforts to remove this reproach, but a careful compilation such as this brings out the fact that even now we are very imperfectly acquainted with the constitution of cast iron, and therefore with the means of scientific control of its properties For example, the relations between the sulphur and manganese contents of the iron are of the greatest importance in determining the degree of chill under given conditions, but the evidence is contradictory, and published work on the subject goes little beyond the knowledge of practical foundrymen Even the relations between graphite, combined carbon, and silicon cannot yet be represented in a simple and intelligible diagram, and arbitrary assumptions have to be made concerning them

Dr Hatfield has included almost all that has been done on the subject, except in regard to the so called 'pearlitic' irons, which might have received fuller treatment, and the new edition is valuable as a work of reference on a much neglected field of metallurgy Unfortunately, the references in the foot notes are frequently incorrect, probably through imperfect proof reading, and the student who attempts to consult original papers may find himself at a loss Apart from this defect, however, the book is to be commended to metallurgists as a compendium of facts When the fourth edition is called for, it may be hoped that such progress will have been made in the scientific knowledge of cast iron that a systematic presentation of its metallography is possible

C H D

A Bibliography of Metallic Corrosion comprising References to Papers on Ferrous and Non-Ferrous Corrosion (including Methods of Protection) published up to end of 1927 Greatly enlarged from a Bibliography prepared for the British Non Ferrous Metals Research Association and privately issued to its Members By Dr W H J Vernon Pp xi + 341 (London Edward Arnold and Co, 1928) 21*s* net

THE literature of corrosion is extensive and at the same time widely scattered, so that a student of the subject feels the need of a bibliography more than in most branches of applied physical chemistry Several attempts at such a compilation have been made, but certainly with less success than in the present work, which is likely to prove of great value to chemists and to metallurgists At first sight it may be thought that the classification which Dr Vernon has adopted is not the simplest, since there is no alphabetical index of authors, and the arrangement is one of many sections, each of which covers a definite part of the subject After using the book for a short time, however, it is found that there is no difficulty in tracing any required paper the author of which is known, whilst a thorough system of cross references ensures that the papers likely to have a bearing on any particular question can be traced with little effort The bibliography has responded well to the test of looking for known memoirs

There is no attempt to give the exact title of each paper, a short indication of the subject being given in English, but the original reference is accompanied by references to abstracts in the most accessible English and American journals When necessary, a brief abstract is added, and this part of the work has been done judiciously, so that the reader is guided to essential papers without having to consult a large mass of material of no importance to his immediate subject Dr Vernon is to be congratulated on having performed a useful task with success

C H D

Miscellany

History and Historical Research By C G Crump Pp x + 178 (London George Routledge and Sons, Ltd, 1928) 5*s* net

THIS is a delightful and stimulating little book Mr Crump held an important position in the Public Record Office for many years, but he writes in a spirit which would be equally becoming in a scientific laboratory In fact, his essay is one of the best proofs we have seen of the essential similarity between all forms of work which aim at increasing knowledge of a living kind Almost everything he says might be said with equal truth about scientific research

Mr Crump starts with the primary and fundamental necessity of an inquiring mind Every researcher must be possessed with the desire to know In this he only shares the characteristic which Aristotle assigned to the human species as a whole, when he adds to this the mark of wanting to know something new, or more about something than anyone else knows, he takes rank among original researchers—those who add to the sum of human knowledge But in order to do this he must at starting be provided with a considerable equipment of general knowledge, and no part of Mr Crump's book is better than where he dwells on the supreme importance of a well trained mind in judging of the likely field for research and of the value of evidence, and in presenting it in a lucid and well ordered form

Two other admirable features stand out in this manual for the young researcher One is the insistence on self reliance The choice of subject must be individual, and the professor, or older and more experienced colleague, should assist as friend and equal, not as dictator or superior All the details of his method—the note taking, and arrangement, the planning and writing of the book—will be subordinate to the main idea, and grow under his hand as he works In short, the researcher, be he historian or man of science, is master of his own fate, and no one can make or mar it but himself

Another attractive feature of the book is the style in which it is written, and the constant quiet humour which irradiates the whole There is no better example of this than the analogy of the choice of a subject with the chase of a lion The researcher has first to delimit the area in which he may find his quarry This in itself demands wide knowledge and careful preliminary survey by these the true haunts of the subject are ascertained The searcher then advances, slowly and steadily testing and securing all the means of approach, and when at last the noble object of his quest stands before him, he is just as likely to be devoured by the quarry as to make it his own The former indeed may seem as fine and fitting a reward as the latter

F S M

The Evolution and Classification of Soils By Dr E Ramann Translated by Dr C L Whittles Pp xii + 127 (Cambridge W Heffer and Sons, Ltd, London Simpkin Marshall, Ltd, 1928) 7*s* 6*d* net

STARTING with a definition of soil, the author brings together many of the ideas and systems which have been developed throughout the world for its scientific classification After discussing briefly the advantages and disadvantages of various methods of classifying soils, a system is adopted which, although almost too wide for general use, is not subject to the serious limitations of most of the older classifications A soil is classified in accordance with its 'zone' (latitude and longitude) and its 'region' (depending on height, position, humid or arid climate, etc)

Most soil workers nowadays have a little knowledge of the Russian pedological classifications and nomenclature, and this has proved in many cases a dangerous thing Those who want to know the exact meaning of *podsol*, *tschernosem*, and similar terms frequently used and mis used in recent works

on soils will find an excellent discussion on the subject in this book, although the author wisely avoids too drastic a use of modern Russian systems Soils are but short lived things compared with their geological neighbours, and our knowledge of their characteristics in bygone times is still scanty—but the paragraph on "Relic Soils" whets our appetite for more

The translation, in spite of great difficulties, reads easily Only one slight improvement might well have been made, it would have been better to have anglicised the transliteration of Russian names—the German transliterations offend the eye in an English book and are very apt to be mis leading

The Great Betrayal (*La Trahison des clercs*) By Julien Benda Translated by Richard Aldington Pp x + 188 (London George Routledge and Sons, Ltd, 1928) 7*s* 6*d* net

THE thesis of M Benda's book is that the European *intelligentsia* have gone over to the enemy, that is to say, they have deserted the idealist ranks and joined the great army of the Philistines It is not merely that the *intelligentsia* have become sceptics they have actually transferred their allegiance, and devote themselves to detract and deride every form of idealism For example, they lend themselves to "the intellectual organisation of political hatreds," and preach the doctrine of "sacred egotism" They display "the scorn for argument, the excess, the hatred, the fixed ideas" which we are ac customed to associate with the lowest forms of political propaganda In short, they have pros tituted their powers, and have become the militia of materialism Even internationalism, which assumes imposing idealist airs, is inspired by bankers, industrialists, and trade unionists, whose aims are by no means disinterested

The most notable betrayal has been an attack upon the intellectual ideal of truth itself, since "truth is a great impediment" There is now, for example, "a bourgeois truth and a working-class truth," and truth varies with frontiers "Recently certain French thinkers waxed indignant that the doctrines of Einstein were accepted by their com patriots without more resistance" There is doubt less much ground for M Benda's onslaught in some continental countries But we do not think that British men of letters or of science have yet reached this stage of cynical barbarism Yet the book is well worth reading The translation is good

J C H

Physics.

Modern Physics By Prof H A Wilson (The Student's Physics, Vol 6) Pp xiv + 381 (London, Glasgow and Bombay Blackie and Son, Ltd, 1928) 30*s* net

PROF H A WILSON is best known for his experi mental researches, but this book shows that he is also able to give clear expositions of the more theoretical aspects of modern physics As he has himself recognised, the title is elastic, and not every-one will agree with his interpretation of it In particular, most examinations demand a greater knowledge of the newer experimental methods and less of mathematical physics than is given here The outlines of electromagnetic theory and electron theory are especially good, and furnish an excellent introduction to more pretentious treatises, whilst the two chapters on relativity are complete in them-selves The sections on the conduction of elec-tricity through gases are good so far as they go, especially the chapter on flames, but too great weight has been given to the work of the Oxford school, and the treatment of the glow discharge could well have been entirely replaced by an account of the precise methods for studying ionised gases at low pressures that have been developed in the last few years at Schenectady and at Princeton, the potentialities of which have still to be properly recognised

The same general criticism applies to the other parts of the book that have an experimental bias What is given is, nevertheless, concise and accurate We have noticed only one incorrect statement the photographing of the artificial disintegration of a nitrogen nucleus is erroneously attributed to Chad-wick in the text (p 225), an obvious slip, since the proper acknowledgment is made to Blackett on the corresponding plate (p 131)

An Introduction to Physical Science By Dr Ivor B Hart Second edition Pp xii + 406 (Oxford Clarendon Press, London Oxford University Press, 1928) 4*s*

An Introduction to Physical Science By Prof James Rice (Benn's Sixpenny Library, No 115) Pp 79 (London Ernest Benn, Ltd, 1928) 6*d*

THOUGH of the same title, these two books differ widely in treatment and in aim The former, now in its second edition, has already proved useful for beginners in experimental science Mechanics, heat, light, sound, and magnetism and electricity all find a place in its pages, the young student being introduced to these sections in some fifty experi-ments which he is himself to work through De-scriptions of numerous demonstrations and appli-cations are also included, the whole being put together in a perfectly natural manner which cannot fail to attract The arrangement is ex-cellent, and the book is cheap at the price

Prof James Rice's book reads more like a retro-spect than an introduction To comment ade-quately on all the main branches of physics within seventy small pages requires very close packing We cannot help feeling that the little book would demand a greater effort of concentration than the majority of uninstructed laymen would be willing or able to make It does, however, provide a pleasant evening's reading for one who already knows, and it might with advantage be put into the hands of students at about the intermediate stage, for the purpose of providing a general survey of past work

An Introduction to Advanced Heat By Dr Ivor B Hart (Bell's Natural Science Series) Pp vii + 336 (London G Bell and Sons, Ltd, 1928) 7s

THE title of this book has been chosen to indicate a standard beyond that usually reached in schools but somewhat below that expected of candidates for the highest honours in the first university degrees The author assumes that his readers really know their elementary work, and even so they must draw a deep breath before plunging into the first chapter, which deals fully with the various scales of temperature

Avoiding the snare of descriptive writing, the author sticks rigidly to his purpose of developing the theory of the subject until he has dealt adequately with the expansion of gases, both from the kinetic and the thermodynamic points of view All this makes rather stiff reading but the conscientious student can scarcely fail to have the satisfactory feeling that he is really plumbing the depths of his subject He will find himself rewarded, at the end, by some more readable chapters, of which perhaps the best—certainly the most novel—is one relating to convection in the atmosphere

Dr Ivor Hart has already achieved prominence as a writer of more elementary books and as a biographer In this latest excursion he is likely to be equally successful

Intermediate Electricity and Magnetism By Dr R A Houstoun Pp x + 170 (London Longmans, Green and Co, Ltd, 1928) 4s 6d

THE title clearly indicates the scope of this book Although it is written on conventional lines, there are many points in the arrangement which make for the orderly development of the subject in a student's mind, the sequence of the reading being unbroken by tedious descriptions of experiments and by reiteration in applications and examples By concentrating in the earlier portion of the book upon the elucidation of main principles, the author has removed from the pupil the difficulty of sorting out the grain from the chaff—it is all good stuff The technical applications of electricity, radio activity, and 'wireless' are reserved for the end of the volume, after the fundamental ideas have already been formed A good collection of questions and examples, inconspicuously printed, help to make up a really useful book

An Outline of Physics By Prof A E Caswell Pp xiv + 773 (New York The Macmillan Co, 1928) 18s net

THIS book is an elementary introduction to physics which is very pleasant to read It is written to appeal to non-mathematical students and to all who are willing to show a passing interest in physics The conceptions necessary to modern physics appear quite early in its pages, and by gradual stages the reader is introduced to many of the most striking and most important results of modern research Analogies are given freely—perhaps too freely, it may be felt, in one or two instances, but the author is always clear, and his final chapter, on the theory of relativity, is exceptionally well written

War Office Elementary Notes on Optics and their Application to Service Instruments Compiled for Use in the Rangefinding Branch, Military College of Science, Woolwich, 1927 Pp 128 (London H M Stationery Office, 1927) 3s net

A USEFUL little book which should fulfil its purpose very well, and give the military student of optics the guidance he needs in understanding the construction of his instruments It may be suggested that the treatment of simple lenses is a little brief, a fuller discussion of the magnification at various conjugate distances would have been valuable when dealing with variable power telescopes Also, in spite of the limitations of space, a few remarks on spectacles and on colour filters would have been useful to the service student

Primary Physical Science By William R Bower Pp ix + 302 (London Sir Isaac Pitman and Sons, Ltd, 1928) 5s

THE book deals with the rudiments of mechanics, heat, and chemistry along the lines laid down for the examination in preliminary technical science of the Union of Lancashire and Cheshire Institutions For the most part the treatment is conventional but good historical and biological notes are included The book suffers from a certain lack of continuity in the reading, as is almost inevitable when a work serves the purpose of a laboratory manual, a text book, a history of science, and a book of exercises, all in one

Laboratory Physics a Short Course By H W Heckstall Smith and B A Fletcher Pp vii + 224 (Oxford Clarendon Press, London Oxford University Press, 1928) 4s 6d

THIS book is intended for use in all the laboratory work in physics which is necessary for the higher certificate examinations Although there is little that is novel in the experiments which are described, the whole book is excellently arranged and it should tend towards good, orderly work in a school laboratory It would also serve as a useful guide in any school where an advanced course in science is being developed

Physiology

A Text book of Physiology By Prof William D Zoethout Third edition Pp 664 (London Henry Kimpton, 1928) 18s net

Laboratory Experiments in Physiology By Prof W D. Zoethout Pp 251 (London Henry Kimpton, 1928) 10s 6d net

THESE two books may be considered as complementary In the text book the author has set out to give an account of physiology suitable for dental students, and has attempted to steer his course between the larger text-books and the shorter elementary treatises The work has reached its third edition in the course of a decade and has been thoroughly revised, it appears to be well up to date The selection of material for such a book must be largely a matter of opinion, and depends in part on the courses required of the

students for whom it is intended, it may be recommended to all those who do not wish to read one of the larger works

The other volume gives a fairly detailed account of experimental class physiology, including also a short section on chemical physiology The experiments, however, are often unsuitable for a practical course in Great Britain, since they require the use of anæsthetised animals as subjects, some, doubtless, with suitable modifications could be carried out on the surviving carcass Apart from this objection, the experiments described appear to cover the ground fairly completely and are probably more detailed than required by the average medical student A number of the illustrations are taken from Jackson's "Experimental Pharmacology"

The A B C of Vitamins By John Pryde (The Vanguard Series) Pp 128 (London John Hamilton, Ltd, 1928) 2*s* 6*d* net

THE aim of this short readable volume is to give the non scientific reader a simple account of our present knowledge of the vitamins in non technical language The author appears to have succeeded very well in conveying the essentials of a complex subject to its pages, and the book should enable the numerous people who take an interest in their diet to choose appropriate foodstuffs or to exercise discrimination in their selection of a proprietary 'vitamin food' We note that the author refers to vitamin B_2 as the growth promoting fraction of vitamin B, as a matter of fact, animals, young rats for example, will fail to grow unless vitamin B_1 is supplied in the diet as well as vitamin B_2, so that both fractions are necessary for growth Also it is stated that mammalian liver contains vitamins A and D it appears probable that the latter is absent from mammalian liver, although fish livers provide a rich source of this vitamin These criticisms, however, detract in no way from the usefulness of the book to those who wish to regulate their diet, but people should not be advised to give themselves ultra violet irradiation in their own homes, owing to the dangers of possible over exposure The book is quickly read and can be recommended to the intelligent layman for perusal

Übungen aus der vergleichenden Physiologie Atmung, Verdauung, Blut, Stoffwechsel, Kreislauf, Nervenmuskelsystem Von Hermann J Jordan Unter Mitwirkung von G Chr Hirsch Pp viii + 272 (Berlin Julius Springer, 1927) 18 gold marks

THIS manual gives the course of laboratory exercises in comparative physiology which the authors have evolved for students of biology in their laboratory at Utrecht Experiments have been selected which are readily performed by the student and require only easily obtainable biological specimens and apparatus, wherever possible, of a simple rather than of a costly character The book deserves the attention of zoologists, since it is primarily biological and not merely an adaptation of medical physiology

Psychology

An Historical Introduction to Modern Psychology By Dr Gardner Murphy With a Supplement by Dr Heinrich Klüver (International Library of Psychology, Philosophy, and Scientific Method) Pp xvii + 470 (London Kegan Paul and Co, Ltd, New York Harcourt, Brace and Co, Inc, 1928) 21*s* net

A PRELIMINARY glance at this very substantial volume—one of the largest in the important series to which it belongs—might cause one to wonder at certain of its features Why, for example, should several pages be devoted to Alexander Bain, and only a few words to James Ward? The answer to this question reveals one of the many limitations which the unquestionably learned author has imposed upon himself Bain stood strongly for the physiological approach, whereas Ward's contribution, though equally distinctive, consisted in applying evolutionary concepts to introspective analysis, and Dr Murphy's main concern is to trace the changes which have led to an increasing emphasis upon the objective method of study, which has passed from the physiological to the experimental and quantitative methods so assiduously cultivated to day It is for this reason that such a thinker as Ward does not come much into Dr Murphy's picture The author has provided a most interesting and satisfying account of modern psychological developments in Europe and America In a supplement, Dr Kluver shows how recent German psychology has proceeded on lines of its own

Practice Fatigue and Oscillation a Study of Work at High Pressure By J C Flügel (*British Journal of Psychology*, Monograph Supplements, 13) Pp v + 92 (Cambridge At the University Press, 1928) 8*s* 6*d* net

THIS is the latest addition to the series of monograph supplements issued in connexion with the *British Journal of Psychology*, and is a good example of the kind of work which is being done by the scientific or objective school of psychologists at the present time—a school which has found great favour in America, but less in Great Britain 'Fatigue' and 'practice,' and the relations between them, are familiar subjects of experimental investigation By 'oscillation' is meant those short period variations in efficiency usually referred to as fluctuations of attention

Mr Flügel's object has been to experiment, on a larger scale than has hitherto been attempted, with the view of discovering any general characteristics of these three functions, and also to apply statistical methods to the study of their inter-relationships The thoroughness of his procedure, the extreme caution with which inferences are drawn, and the frank admission, or rather insistence, that complete success was not achieved in carrying out a rather ambitious programme, are all in the most exacting spirit of scientific method It is on such studies as these that an important group of modern psychologists have hopes of real advance

The Child in Primitive Society By Prof Nathan Miller (Library of Educational Psychology) Pp v+307 (London Kegan Paul and Co, Ltd, 1928) 12s 6d net

THE scientific study of childhood assumes several different aspects, of which the physiological and the psychological have received much attention for several decades past The sociological study of the child has not come so definitely to the front, although A F Chamberlain's book, "The Child a Study in the Evolution of Man," stands as a good specimen of what could be done in this field a generation ago Dr Nathan Miller's is a timely addition to contemporary literature on the subject

For the educator the value of the work before us lies in the fact that the position of the child in a modern complex society is made clearer by an examination of the part he plays in primitive society From the broad scientific view such a study is of value because of the light it throws upon the mechanism of social heredity, for in the absence of a written language the child has necessarily been the chief means of perpetuating culture from one generation to another Dr Miller has used the method employed by Spencer, Frazer, Tylor, and others—the method of drawing upon the immense body of facts collected by trained observers, and by travellers among people of simple cultures A most interesting and stimulating treatise is fortified by an extensive bibliography

Technology

Practical Color Simplified a Handbook on Lacquering, Enameling, Coloring, and Painting, with special attention to Mixing, Choosing, Harmonising, Matching, Lighting, Testing, and Designation By William J Miskelle (Practical Finishing Series, Vol 1) Pp xiii + 113 + 10 plates (Chicago Finishing Research Laboratories, Inc, 1928) n p

THIS book sets out to provide a guide to a great many problems for the practical colourist, but in spite of its somewhat ambitious presentation of a colour circle, mixing triangle, harmonising triangle, and so on, there will be little to be gathered beyond the usual elementary facts of subtractive colour mixture that could not be very much more effectively learned by a really scientific approach to the subject Arbitrary directions to mix so many parts of 'red' with so much 'blue' are apt to be misleading unless the mixer knows something about the red and blue to select A knowledge of the spectral transmission or reflective coefficients of pigments, some notions of their relative staining powers, and the like, would form a very much sounder basis on which to build a discussion of real colour mixture

The writer brings in some discussion of 'wavelengths' (he should note that μ stands for one micron, *not* a milli micron) and has something to say on nearly everything from 'Shakespeare' to 'Old Glory,' but when in his chapter on "Colour Photography" (which ought to be headed "The Photography of Colours") he laments that "panchromatic plates are not generally available for the use of either roll film cameras or the amateur photographer," he must be prepared to make readers of NATURE somewhat nervous of his leadership The book may be of some help to those who are prepared to accept his interesting methods of selecting colour harmonies

Photographic Art Secrets with a General Discussion of Processes By Dr Wallace Nutting Pp x + 133 + 105 plates (London Chapman and Hall, Ltd, n d) 12s 6d net

'THE author has made many millions of photographs," although he confirms the statement that "there are only two perfect photographic days in the year," and in this volume gives his experiences in a series of ejaculatory statements of facts and opinions, but unfortunately does not distinguish between the two He acknowledges that his *secrets* "may not be secrets to all who use cameras," but finds that the average amateur photographer does not know, or at least does not use his knowledge, of these matters Scientific facts given are very few, this side of the art being evidently weak with the author, for example, he says 'a plate consists of microscopic particles of nitrate of silver in an emulsion of gelatine" The author condemns exposure meters as requiring judgment in their use, 'bothersome also because to consult it requires time," and 'it is often impossible to use" Instead, he gives a table of proportional exposures according to the time of day and year, climatic conditions, and the character of the subject We cannot indicate all the topics dealt with, as there are forty two of them, these and the numerous illustrations, many of which are very nice and bear evidence to the author's skill, form a book that contains many useful suggestions that will inform the ignorant and refresh the memory of others

The Finishing of Jute and Linen Fabrics By Thomas Woodhouse Pp xxi + 346 (London Macmillan and Co, Ltd, 1928) 18s net

THE second edition of this standard work, which was originally published at 8s 6d, now makes its appearance at a considerably increased price Unfortunately, a careful comparison of the new and old texts does not reveal as much new treatment of the original subject matter as one is led to expect from the preface Nevertheless, several new features appear in connexion with recent developments in the various kinds of machines which are described, particularly in the case of bag sewing machines References are made to modern applications of electric driving and heating, to safety devices, and to improved methods of mechanical adjustment In addition, the chapter on waterproofing and fireproofing has been almost completely rewritten

The author's work is usually characterised by excellent diagrams and illustrations, and this book is no exception

Forthcoming Books of Science.

Agriculture, Forestry, and Horticulture

Ernest Benn, Ltd —The English Grass Orchard, A H Hoare, Farm Crops, A W Oldershaw and J Porter *Jonathan Cape, Ltd* —A Modern Herbal, edited by Mrs C F Leyel 2 vols *Chapman and Hall, Ltd* —The Structure and Life of Forest Trees, an English translation of "Bau und Leben Unserer Waldbäume," Prof M Busgen, third edition, revised by Prof E Münch, translated by T Thomson *Gurney and Jackson* —The Crop Grower's Companion J Porter *Macmillan and Co, Ltd* —Text Book of Tropical Agriculture, Sir H A A Nicholls, second edition revised by J H Holland

Anthropology and Archæology

G Allen and Unwin, Ltd —Memories of My Life, Prof E A Westermarck, The "Soul" of the Primitive, Prof L Lévy Bruhl, translated by Lilian A Clare, The Origin and Development of Nationality, Dr B Joseph *Cambridge University Press* —Our Forefathers The Gothonic Nations, G Schütte *Jonathan Cape, Ltd* — The Heritage of Man, H J Massingham, Modern Chinese Civilisation Dr A F Legendre The Story of the Gypsies, K Bercovici *Longmans and Co, Ltd* — Race and Population Problems, Dr H G Duncan, Poverty, R Kelso (Longmans' Social Science Series) *Methuen and Co, Ltd* —Studies of Savages and Sex, A E Crawley, edited by T Besterman *Oxford University Press* —The Danube in Prehistory, Prof V Gordon Childe, Ashanti Law and Constitution, Capt R S Rattray Examples of Maya Pottery in the Museum and Other Collections edited by the late G B Gordon, Part 2 Rock Paintings of Southern Andalusia, the Abbé H Breuil and M C Burkitt, with the collaboration of Sir Montagu Pollock Bart, Biblical Anthropology, compared with and illustrated by the Folklore of Europe and the Customs of Primitive Peoples H J D Astley *Kegan Paul and Co, Ltd* —The Mongol in Our Midst a Study of Man and his Three Faces, Dr F G Crookshank, new edition, Witch Hunting and Witch Trials, collected and edited, with an Introduction, by C L Ewen Greek Thought, and the Origins of the Scientific Spirit Prof L Robin, The Court of Burgundy, O Cartellieri, Life and Work in Prehistoric Times, Prof G Renard (The History of Civilisation Series) *Williams and Norgate, Ltd* —The Antiquity of Man, Sir Arthur Keith, 2 vols, new edition, Further Discoveries in the Antiquity of Man, Sir Arthur Keith

Biology

Cambridge University Press —Anatomy and the Problem of Behaviour, G E Coghill, An Introduction to the Study of Bird Behaviour, H Eliot Howard *Hodder and Stoughton, Ltd* —How to Enjoy Birds, M Woodward. *Oliver and Boyd* —Dictionary of Scientific Terms, Pronunciation, Derivation, and Definition of Terms in Biology, Botany, Zoology, Anatomy, Cytology, Embryology, Physiology, I F Henderson and Dr W D Henderson, second edition, revised and enlarged *Oxford University Press* —The Story of Our Knowledge of Living Things The Evolution of Biology Dr C Singer, Index Londinensis, an emended and enlarged edition continued up to the end of the year 1920 of Pritzel's Alphabetical Register of Representations of Flowering Plants and Ferns, Dr O Stapf, six volumes, vols. 1 and 2, The Plant Life of the Balkan Peninsula A Phytogeographical Study, Dr W B Turrill, The Story of the Mosquito, J A. Crawford and B S Chalam; Plant Hybridisation before Mendel, H F Roberts; The Principles of Systematic Entomology, G F Ferris *Kegan Paul and Co, Ltd* —Contributions to the Principles of Morphology, Dr W B Crow *G P Putnam's Sons, Ltd* —Our Face from Fish to Man, Prof W K Gregory *G Routledge and Sons, Ltd* —Insect Singers: a Natural History of the Cicadas, Dr J G Myers, Ants, Bees and Wasps, Lord Avebury, new edition, edited by Dr J G Myers, Blue Blood in Animals, Prof H Munro Fox, Queer Fish Essays in Marine Biology, Dr C M Yonge *Sheldon Press* —Nature in Field and Meadow, W P Westell *University of London Press, Ltd* —Animal Psychology for Biologists, Dr J A Bierens de Haar *Williams and Norgate, Ltd* —How Birds Live, E M Nicholson, new edition.

Chemistry

Ernest Benn, Ltd —The General Principles of Chemical Engineering, Prof S G M Ure, The Chemistry and Manufacture of Pigments and Paints, C A Klein, 2 vols. *Cambridge University Press* —Molecular Rays, R Fraser (Cambridge Series of Physical Chemistry) Elementary Qualitative and Volumetric Analysis, N F Watterson. *Chapman and Hall, Ltd* —Hydrogen Ion Concentrations: their Determination and Industrial Importance, Dr H T S Britton, Industrial Carbon, Dr C L Mantell, Electrochemistry, C J Brockman, Dusts, Smokes, Fumes and Odours in Industry, P E Landolt, The Liquefaction of Coal, F C Whitmore, Cracking of Petroleum W F Faragher, Colloid Chemistry, J Alexander (Industrial Chemical Monographs) *C Griffin and Co, Ltd* —The Analysis of Drugs and Chemicals, N Evers and G D Elsdon Vanadium, Niobium and Tantalum, S Marks (Friend's Inorganic Chemistry, Vol 6, Part 3) *Crosby Lockwood and Son* —Applied Chemistry A Practical Handbook for Students of Household Science and Public Health, Dr C K Tinkler and Helen Masters, Vol 1, Water, Detergents, Textiles, Fuels, etc *Methuen and Co Ltd* —A Concise Summary of Elementary Organic Chemistry, Dr F H Constable

Engineering

Ernest Benn, Ltd —Motive Power and the Modern Steam Turbine, Hon Sir Charles Parsons and R Dawson, Insulated Electric Cables, C J Beaver, 3 Parts, Electrical Measuring Instruments, Dr C V Drysdale and A C Jolley Part 3 Steady Current Laboratory Instruments, Part 4 Alternating Current Laboratory Instruments, The Electrification of Railways, R Smith, Rotary Convertors, T P Whittaker *Chapman and Hall, Ltd* — Electrical Engineering Practice, J W Meares and R E Neale, Vol 3, new edition, Telegraphy and Telephony, including Wireless Communication, Prof E Mallett, Steam Turbines, Eng Lieut Comdr T M Naylor *Constable and Co, Ltd* —Practical Design of Simple Steel Structures, D Stewart, Vibration Problems in Engineering, S Timoshenko *C Griffin and Co, Ltd* —Questions and Answers on the Construction and Operation of Diesel, Semi Diesel, and other Internal Combustion Engines, etc, J Lamb, new edition, The Balancing of Oil Engines in Theory and in Practice, W K Wilson, A Text book on Surveying and Levelling, H Threlfall, new edition, with new supplement on photographic surveying *Crosby Lockwood and Son* —Surveying as Practised by Civil Engineers and Surveyors, J Whitelaw, new edition, revised and enlarged by Sir Gordon Hearn, Industrial Refrigeration, Cold Storage, and Ice Making, A J Wallis Tayler, Railway and Seaport Freight Movement, comprising Modern British and North American Practice, G Bulkeley, Kempe's Engineer's Year Book, 1929 *Longmans and Co, Ltd* —The Theory of Heat Engines, W Inchley, third edition, revised by Dr A Morley *Macmillan and Co, Ltd* —Gauges and Fine Measurements, F H Rolt, with Introductory Note by J E Sears, Junr, and edited by Sir Richard Glazebrook, 2 vols, Theory of the Gyroscopic Compass, Dr A L Rawlings *Methuen and Co, Ltd* — Astronomy for Surveyors, Prof M K Rice Oxley and W V Shearer, Engineering Wonders, E Hawks; The Ventilation of Mines The Generation of the Air Current, Prof H Briggs, Mechanical Engineering for Mining Students, J T Wight, Accidents in Mines, Prof J A S Ritson and T Brown *Oxford University Press* —Differential Equations of Engineering Science, P Field Foster and F J Baker, Electro Magnetic Problems in Electrical Engineering, B S Hague, Simple Examples of Constructional Steelwork, Dr O Faber

Geography and Travel.

Cambridge University Press —Some Notable Surveyors and Mapmakers of the XVI, XVII and XVIII Centuries, Sir H George Fordham, People of Other Lands, Books 1 and 2, E D Laborde (Cambridge Elementary Geographies) *Jonathan Cape, Ltd* —The New Map of South America, Dr H A Gibbons. *G G Harrap and Co, Ltd* —The Polar Regions in the Twentieth Century their Discovery and Industrial Evolution, Major General A W Greely *Macmillan and Co, Ltd* —On Alexander's Track to the Indus, Sir Aurel Stein *Methuen and Co, Ltd* —The Ancient Explorers, Dr M Cary and E H Warmington, Asia A Regional and Economic Geography, Dr L Dudley Stamp *Oxford University Press* —An Historical Geography of Europe, J M Thompson, China the Land and the People, L H Dudley Buxton, with a chapter on Climate by W G Kendrew; The Land of Gods and Earthquakes, D Haring *Sheldon Press* —Pitcairn Island Register Book, edited by Sir Charles Lucas

Geology, Mineralogy, and Mining

Ernest Benn, Ltd —The Mechanical Principles of Mining Appliances, Prof H Louis and Dr J Morrow, Mineral Deposits, Prof H Louis, Coal-cutting Machinery and its Applications, S Mavor, Haulage and Winding, H M Morgans *Cambridge University Press* —Earth Flexures, H G Busk *Macmillan and Co, Ltd* —Text Book of Palæontology, Prof K A Von Zittel, English translation, second edition, Vol 2, Pisces—Amphibia—Reptilia—Aves, revised with additions by Sir Arthur Smith Woodward *Methuen and Co, Ltd* —The Nappe Theory in the Alps, Prof F Heritsch, translated by Prof P G H Boswell Mine Atmospheres, Prof I C F Statham and W Payman *T Murby and Co* —Sedimentary Petrography, H B Milner, second edition, Instructions for Using the Quantitative Mineralogical Classification of Eruptive Rocks, Dr S J Shand, Handbook of the Geology of Great Britain, edited by Dr J W Evans and Dr C J Stubblefield, Typical American Oilfields, a symposium prepared by the American Association of Petroleum Geologists, Method in Geological Surveying, Dr E Greenly and Dr H Williams, Tertiary Faunas, Dr A Morley Davies, Block Models, Dr F Smithson *Oliver and Boyd* —The Platinum Deposits of South Africa, Dr P A Wagner, with a special chapter on The Mineragraphy and Spectrography of the Sulphidic Ores of the Bushveld Igneous Complex by Prof H Schneiderhöhn *Oxford University Press* —Petroleum and Coal the Keys to the Future, W T Thom, The Evolution of the Igneous Rocks, N L Bowen *G P Putnam's Sons, Ltd* —The Natural History of Central Asia, Being the Reports of the Central Asiatic Expeditions of the American Museum of Natural History Narrative, R C Andrews, Geology of Mongolia, C P Berkey and F K Morris, Topographic Maps, Kalgan to Orok Nor, L B Roberts, Permian of Mongolia, including The Permian Fauna of the Jisu Honguer Limestone of Mongolia, A W Grabau

Mathematical and Physical Sciences

Ernest Benn, Ltd —The Ether of Space, Sir Oliver Lodge *Cambridge University Press* —Mathematical and Physical Papers, Sir Joseph Larmor, 2 vols, Statistical Mechanics, R H Fowler; Applied Geophysics in the Search for Minerals, Prof A S Eve and D A Keys; Light an Introductory Text book, C G Vernon, Cambridge Intermediate Mathematics, H J Larcombe, The Cambridge New Elementary Arithmetics, J H Webster, new edition *Constable and Co, Ltd* —Introduction to Statistical Mechanics, Dr J Rice *Macmillan and Co, Ltd* —Preston's Theory of Heat, fourth edition, edited by J R Cotter, Lectures on Theoretical Physics, Prof H A Lorentz, translated by Dr L Silberstein and A P H Trivelli, Vol 3 The Principle of Relativity for Uniform Translations (Special Theory of Relativity) *Methuen and Co, Ltd* —The Physical Principles of Wireless, J A Ratcliffe; The Conduction of Electricity through Gases, Dr K. G Emeléus; The Geometry of *N* Dimensions, Prof D M. Y Sommerville; Examples in Applied Mathematics, R O Street *Oxford University Press* —Mathematics for Students of Technology, Junior Course, L. B Benny, Advanced Mathematics for Students of Physics and Engineering, D Humphrey, Problems in Technical Mathematics, A H Stuart, Worked Examples in Electrical Technology, F Peasgood and H J Boyland *University of London Press, Ltd* —The Elements of Mechanics, W D Hills, Mechanics and Applied Mathematics, W D Hills

Medical Science

G Allen and Unwin, Ltd —Health, Disease, and Integration, Dr H P Newsholme *J and A Churchill* —The Physics of X Ray Therapy, W V Mayneord, A Text book of Materia Medica, Prof H G Greenish, new edition, A Practical Guide to the Schick Test and Diphtheria, Dr G Bousfield, Surgical Radiology A P Bertwistle, Recent Advances in Ophthalmology, W S Duke Elder, new edition, Recent Advances in Cardiology, Dr C F T East and Dr C W C Bain, Recent Advances in Pulmonary Tuberculosis, Dr L S T Burrell *Constable and Co, Ltd* —Text book of Pulmonary Tuberculosis for Students, R C Wingfield, Heart Disease, Drs H B Russell and C K S Hamilton *E and S Livingstone* —A Handbook of Practical Therapeutics, Dr D Campbell, A Text book of Public Health, Prof J R Currie, Handbook of Infectious Diseases, Dr D S Sutherland *Longmans and Co, Ltd* —The Heart, Prof T Walmsley, being Vol 4, Part 3, of Quain's Elements of Anatomy, Essentials of Physiology, Prof Eric Ponder *Oxford University Press* —The Work of Medical Women in India, Dr M I Balfour and Dr Ruth Young *University of London Press, Ltd* —The Properties of Food, Prof V H Mottram and Miss W M Clifford

Metallurgy

Ernest Benn, Ltd —Industrial Steel and Iron their Constitution and Properties, P Oberhoffer, translated by W Austin *Chapman and Hall, Ltd* —Select Methods of Metallurgical Analysis, W A Naish and J E Clennell, Practical Steelmaking, W Lister

Miscellany

Cambridge University Press —Stephen Hales D D, F R S an 18th century Biography Dr A E Clark Kennedy *Longmans and Co Ltd* —From the Seen to the Unseen, Rev J H Best *Methuen and Co, Ltd* —Modern Science a General Introduction, Prof J A Thomson

Philosophy and Psychology

G Allen and Unwin, Ltd —Hegel's Science of Logic, translated by W H Johnston and L G Struthers, Identity and Reality, E Meyerson translated by K S Loewenberg *D Appleton and Co* —Psychology and Industrial Efficiency, H H Burtt Bodily Changes in Pain, Hunger, Fear and Rage W B Cannon, new edition, The Art of Straight Thinking a Primer of Scientific Method for Social Inquiry, Dr E L Clarke *Cambridge University Press* —The Idea of Value, Prof J Laird *Hodder and Stoughton, Ltd* —The Sciences and Philosophy, Prof J S Haldane (Gifford Lectures for 1927–28), The Phantom Walls, Sir Oliver Lodge *Macmillan and Co, Ltd* —The Elements of Logic, Prof R Latta and Prof A Macbeath, Formal Logic, J N Keynes, reissue *Oxford University Press* —Matter, Life, and Value, C. E M Joad, Science and Personality, Dr W Brown, Social Psychology The Psychology of Political Domination, C Murchison *Kegan Paul and Co, Ltd* —The A B C of Psychology, C K Ogden, Problems of Individual Psychology, Dr A Adler, Psychology of the Infant, Dr S Bernfeld, An Introduction to Child Psychology, K Bühler (Library of Educational Psychology), Creative Imagination Studies in the Psychology of Literature, Prof June E Downey, The Trauma of Birth, O Rank; Colour and Colour Theories, Christine Ladd Franklin, The Psychology of Philosophers, Dr A Herzberg (International Library of Psychology, Philosophy, and Scientific Method) *G P Putnam's Sons, Ltd.*—Our Minds and Our Motives, P D Hugon

Technology

Ernest Benn, Ltd —The Technology of Sugar Manufacture F C Estick, Electrolytic Alkali, C Elliott; Evaporating, Condensing and Cooling Apparatus, E Hausbrand translated by A C Wright, new edition revised and enlarged by B Heastie, Filtration and Filters, J A Pickard, Encyclopædia of the Ceramic Industries, A B Searle, 3 vols, Modern Brickmaking, A B Searle, new edition, The Chemistry and Physics of Clays and other Ceramic Materials, A B Searle, new edition, Industrial Gaseous Firing, W N Booth, Modern By Product Coking Practice, E Bury and S J Morgan, The History of the Gas Industry, W T Dunn, Industrial Furnace Technique, A Hermansen, Blast Furnace Practice, F Clements, Modern Paper Making, R H Clapperton and W Henderson, Theory and Elements of Architecture, R Atkinson and H Bagenal, Vol 1, 2 Parts, Building Contracting, E L Bird, High Drafting in Cotton Spinning, C Barnshaw, Automatic Looms and Weaving Device, W A Hanton *Cambridge University Press* —Building Craftsmanship in Brick and Tile, and in Stone Slates, N Lloyd, Experimental Building Science, J L Manson and F E Drury, Vol II *C Griffin and Co, Ltd* —Dyeing and Cleaning, F J Farrell, revised by F W Walker, The Clayworker's Handbook, A B Searle, new edition, *Longmans and Co, Ltd* —Applied Design in the Precious Metals, P W Davidson (Longmans' Technical Handicraft Series) *Macmillan and Co, Ltd* —Jute and Jute Spinning, T Woodhouse and P Kilgour, 2 Parts, Part I Cultivation, Preparing and Carding, second edition, Part II Drawing and Roving Frames *Oxford University Press* —Brickwork and its Construction a Text book for all Workers in Brick, the late Walter R Jaggard.

Printed in Great Britain by R & R CLARK, LIMITED *Edinburgh*

neglected by Dalton The formulæ used by Higgins are also more related to modern formulæ than were those of Dalton

SIR ERNEST RUTHERFORD delivered the first of a course of four lectures on "Molecular Motions in Rarefied Gases" on Mar 2 at the Royal Institution. In recent years, much experimental work has been done in this interesting field of inquiry, and the results obtained are not only of theoretical importance but also of practical and industrial interest, as the construction and operation of high speed pumps for production of the lowest vacua and the measurement of the minute pressures depend on an accurate knowledge of the motion of rarefied gases. An account was first given of the historical development of the kinetic theory of gases, with special reference to the early work of Waterston and Joule and the rapid development of the theory in its modern form by Clausius and Maxwell Further progress has been made in recent years by Jeans and Chapman, while the experiments of Knudsen on gases of low pressure have resulted in notable contributions to our knowledge It is only in the last few years that a definite experimental proof has been given of the velocity of molecules in a gas, and of the correctness of Maxwell's famous law of distribution In the lowest vacua obtainable to day, a molecule can travel more than 100 metres without a collision, even though there may still remain 40,000 millions of molecules in every cubic centimetre of the gas

AN experimental Friday evening discourse was given on Mar 1 at the Royal Institution by Sir Robert Robertson After discussing the limitations of other methods of investigating infra red radiations, a modern spectrometer, fitted with thermopile and galvanometer, was described, and by its means an absorption band of a gas (ammonia) was mapped The origin of oscillation and rotation bands was then discussed Oscillation bands are due to vibrations of the atom in a molecule These are reflected in the main bands found in the infra red both in emission and in absorption spectra, and frequently have a harmonic relationship with one another Rotation of the molecule is shown by bands in the far infra red and in the near infra red by fringes imposed on the oscillation bands From the difference in frequency of these fringes the moment of inertia of the rotating molecule can be calculated, from which values for the length of the molecule agreeing with those reached by totally different methods can be obtained Mention was also made of the importance of infra red spectra in the study of radiation given off in the processes of combustion and of explosion, in the investigation of stellar radiation and temperature, and the secular effects of differences in climate due to changes in intensity of solar radiation. Not only does this study afford valuable data for the theoretical physicist from the points of view of the quantum theory and wave mechanics, but also it is becoming increasingly useful for determining chemical structure and suggesting molecular models. The dynamical behaviour of atoms in the molecule, and of the molecule itself as revealed by the study of this region of the spectrum, is a subject worthy of much more attention than is being given to it in Great Britain.

AT the annual general meeting of the Institute of Chemistry of Great Britain and Ireland, held on Mar 1, Dr Harold G Colman presided in the absence of Prof Arthur Smithells, who is on a visit to South Africa The Report of Council showed that the roll of membership of the Institute at the end of January consisted of 1855 fellows and 3703 associates, in addition to nearly 700 registered students The Meldola Medal for 1928 was awarded to Dr J A V Butler, the Sir Edward Frankland Medal and Prize to Cyril Fryer, and the Pedler Scholar for the year is Mr George Morrison Moir The chairman read an address from Prof Smithells, in the course of which he stated that he considers the notion of making chemistry a closed profession is entirely impracticable The Institute has been definitely entrusted with the duty, and already affords the means, of maintaining a register of chemists on which the Government, industry, and the public increasingly rely, but it does not adopt an unsympathetic attitude towards those outside its ranks who can usefully pursue a chemical calling The Institute has every variety of chemist within its ranks and is truly representative of the profession It is a living and growing thing, unconstrained by the rigidity of what is called machinery, and those who have sat at its Council table know that its work is pervaded by common sense and warmed by human feeling The following officers were elected for the ensuing year *President* Prof Arthur Smithells, *Vice Presidents* Mr Arthur J Chapman, Dr G C Clayton, Mr Ernest M Hawkins, Prof G G Henderson, Dr R H Pickard, and Prof J F Thorpe, *Hon Treasurer* Mr Patrick H Kirkaldy

Two items of exceptional interest are recorded in Mr Leonard Woolley's report on recent excavations at Ur (*Times*, Feb 26) The first is a royal burial chamber of the First Dynasty in the form of a complete underground house, 40 ft by 26 ft In it there are four intercommunicating rooms with domed and corbelled roofs The tomb had been plundered, but its importance lies in the fact that it is a new feature in Sumerian funerary custom and, as Mr Woolley suggests, explains the large number of attendants slaughtered at a royal funeral, clearly it was intended that the royal mode of life should be continued in the next world in every particular The second find, which holds out promise of future discovery, is a number of clay nodules with written tablets and clay jar stoppers with archaic sealings Although not so old as the pictographic tablets of Kish, they belong to a period hitherto represented only by rude clay figures of animals and men They were found in a mass of rubbish stretching down from the walls of the earliest Sumerian settlement to the marsh or river In such conditions there is reasonable expectation of finding pictographic material as early as that from Kish The completion of the excavation of the great temple has now laid bare its vicissitudes for the whole period of the 2500 years of its existence

THE electric meter has now been brought to a wonderful pitch of perfection Considering the

hundreds of thousands of them that are continually rotating in Great Britain, it is wonderful that such a minute percentage ever have an average inaccuracy so great as two per cent So accurate are they that they are sometimes used, with the addition of voltage and current transformers, to measure the power delivered by supply companies to tramway and manufacturing companies, meter bills of which amount to hundreds of thousands of pounds per annum In this case, an error of one per cent means thousands of pounds per annum, and hence great precautions have to be taken to secure accuracy Sometimes as many as six meters of various types are put in series and the average reading is taken as the true value Possibly in this way a maximum inaccuracy not exceeding the half of one per cent can be assured In order to secure sustained accuracy in service, it is necessary that the brake magnets remain constant and that the rotor bearings do not wear away The latter problem is considered in a valuable paper read to the Institution of Electrical Engineers on Mar 1 by W Lawson He gives a large number of experimental and statistical data on worn bearings. Various jewels which rank high in the scale of hardness have been utilised for the footstep bearing Garnets, which were formerly used, are now discarded, and rubies and sapphires are generally used It is claimed that artificial rubies and sapphires are more uniform in quality and slightly harder than the natural stones In some cases the hardest known natural substance—diamond—is used and its use is increasing The bearing surface is cupped as in other stones Its manufacture in this form is a highly specialised art The Birmingham Supply Corporation now uses these bearings for its large meters For the last thirty years also they have been used in America

In his annual report to the Department of Overseas Trade (London H M Stationery Office, 5s net) J R Cahill, Commercial Councillor at H M Embassy in Paris, gives an interesting account of the electrical industry in France Much of the prosperity of the country is due to the rapid development of this industry In the manufacturing industry, combination has reached an advanced stage Three or four groups of factories control the whole market Competition, therefore, is not severe, and prices consequently decline at a slower rate The electrification of French railways, particularly the Midi Railway, is making rapid progress In April of 1927 the Midi Railway stated that electrification saved it 130,000 tons of coal every year It now operates 500 miles of its system electrically, and aims at electrifying a further 687 miles in the next five years The total capacity of French power stations is five million kilowatts, of which more than a third is due to water power It operates more than 2000 miles of power transmission lines at pressures not less than 100,000 volts The line connecting Bordeaux and Toulouse, which is 250 miles long, works at 150,000 volts It is interesting to notice that water power is not developing so rapidly as thermal power Possibly this is due to the fact that the prices for hydro-electric energy are State controlled The possibilities in connexion with the extensive lignite deposits not far from Bordeaux for large steam stations are being considered About 30,000 people are now employed for manufacturing radio apparatus. Although French exports of radio apparatus at present considerably exceed the imports, yet a considerable amount of radio accessories, particularly loud speakers, of British and American manufacture, are sold In telephony, the automatic system is being adopted and many long distance multi-core cables have been laid As in Great Britain, the rapid progress of telephony has affected adversely telegraph traffic

A conversazione and exhibition will be held in connexion with the coming-of age celebrations of the Institute of Metals at the Science Museum, South Kensington, S W 7, on Thursday, Mar 14

Dr E J Allen, F R S, secretary of the Marine Biological Association of the United Kingdom and director of the Plymouth Laboratory, will deliver the Hooker Lecture before the Linnean Society on Mar 14, taking as his subject "The Origin of Adaptations"

At the annual general meeting of the Quekett Microscopical Club, held on Feb 12, the following officers were elected for the session 1929 1930 *President* Mr John Ramsbottom, *Vice Presidents* Mr D J Scourfield, Sir David Prain, Dr C Tierney, and Dr W T Calman, *Treasurer* Mr C H Bestow, *Secretary* Mr W S Warton

In commemoration of the bicentenary of Josiah Wedgwood in 1930, the Ceramic Society proposes to publish a volume of essays, for which two prizes are offered The competition is not limited to members of the Society All papers must reach the secretary of the Ceramic Society, North Staffordshire Technical College, Stoke on Trent, by Mar 31, 1930

A special display of the film "With Cobham to the Cape" will be shown in the Empire Marketing Board Cinema at the Imperial Institute on Mar 17 at 2 45 P M and 4 15 P M, and on Mar 18–20 daily at approximately 10 15 and 11 35 A M and 2 15 and 3 35 P M Admission is free, but schools in organised parties are requested to make application for seats to the Secretary, Imperial Institute, South Kensington, S W 7, as early as possible

The Royal Society of Arts is offering two prizes under the Thomas Gray Memorial Trust for the improvement and encouragement of navigation, one, of £150, is for an invention in the years 1928 and 1929 of an improvement in the science or practice of navigation, and the other, £50, is for an essay on the navigation of a low powered steamer in a revolving storm Full particulars can be obtained from the secretary of the Royal Society of Arts, John Street, Adelphi, London, W C 2 The competition closes on Dec 31, 1929

The Council of the Iron and Steel Institute has this year awarded the Bessemer Gold Medal of the Institute to the Honourable Sir Charles A. Parsons, in recognition of his distinguished services in advancing the science of engineering as applied to the manufacture of iron and steel The Williams Prize, of the value of 100 guineas, which was founded for the

encouragement of papers of a practical character by Mr Illtyd Williams on his retirement in 1926, has been awarded in equal portions for the two papers, "Blast Furnace Practice in Natal," by Messrs J E Holgate and R R F Walton, and "The New Plant of the Appleby Iron Co, Ltd," by Messrs A. Crooke and T. Thomson

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A junior engineer under the Safety in Mines Research Board in connexion with research on colliery wire ropes—The Under Secretary for Mines, Establishment Branch, Mines Department, Dean Stanley Street, S W 1 (Mar 15) An assistant for work in connexion with research on water pollution—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S W 1 (Mar 20) A temporary junior forestry inspector under the Government of Northern Ireland—The Secretary, Civil Service Commission, Northern Ireland, 15 Donegall Square West, Belfast (Mar 23) An assistant agricultural chemist at Institute of Agriculture, Kirton—The Principal, Institute of Agriculture, Kirton, near Boston, Lincs (Mar 27) A principal of the new farm institute of the Kent Education Committee at Borden—The Agricultural Organiser, Springfield, Maidstone (Mar 30) A senior lecturer in psychology at the Rhodes University College, Grahamstown—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W C 2 (April 1) Male cartographers in the Hydrographic Department of the Admiralty —The Secretary, Civil Service Commission, Burlington Gardens, W 1 (May 23) A research chemist at the Cardiff City Mental Hospital—The Medical Superintendent, Cardiff City Mental Hospital, Whitchurch, near Cardiff A director of research under the J A C Committee, with graduate qualifications in agriculture, botany, and chemistry, and some experience in conducting field experiments—N Hackett, Kingswood, Bingley, Yorkshire A junior assistant under the directorate of explosives research, Woolwich—The Chief Superintendent, Research Department, Woolwich, S E 18

Our Astronomical Column

JUPITER AND VENUS —On Mar 14 a conjunction of Jupiter with the new moon will be very interesting for two reasons, namely, the near approach of the two bodies, and the convenient hour at which it happens The event will take place on Mar 14, at about 10 P M, at which time Jupiter will be apparently distant from the north limb of the moon about four tenths of a degree only The picture afforded by these objects so near together will be enhanced by the presence of the brilliant planet Venus lying about 10 degrees north west of the others Jupiter is now becoming fainter with increasing distance from the earth, but Venus will attain its maximum brilliancy on Mar 15, and shine with striking lustre amid the twilight of the north west This planet is now travelling sunwards and will disappear from the evening sky after the middle of April, but will return to view in the morning twilight of May

MARCH METEORS —There are no special displays of meteors recurrent in March, but fireballs are fairly prevalent Though meteors are not abundant they will deserve special attention, for March and the other spring months have been much neglected in past years A few careful observations in March are, therefore, worth a large number obtained in the summer or autumn months when investigations in this field have been already conducted to a considerable extent in past years

During about the third week in March, meteoric radiants at $161° + 59°$ and $312° + 79°$ have been occasionally exhibited, and there are really a great number of feeble systems slightly manifested, but possibly many of these are relics of ancient displays now very attenuated by frequent encounters with the terrestrial atmosphere in past ages.

AURORA BOREALIS —On Wednesday evening, Feb 27, an unusual and striking display of aurora was observed from various parts of Great Britain It has been described as the Zodiacal light, but the exhibition appears to have been of too brilliant a character to be considered as formed by the latter phenomenon A correspondent at Burnham-on Sea noticed the strange light just before 10 P M. Its aspect was that of an intensely coloured band stretching across the northern horizon It remained some time and passed slowly in a direction far to the westward The beam was strikingly luminous and finally disappeared soon afterwards

Accounts have come from many stations descriptive of the event and of the change in position and location which the chief feature assumed Several people thought it a remarkable meteoric fireball with very slow motion and long duration

From the south coast of Devonshire, and from Wiltshire and other stations, observers refer to the vivid nature of the spectacle It was first detected at about 9 30 P M and had nearly disappeared from view 20 minutes afterwards Mr B G Hoare, writing from Inverness, states that the display was visible from 8 30 P M until midnight At some stations streamers of pale light ascended from the horizon to considerable heights and were traceable at the zenith Changes constantly affected their intensities and positions The cloud or luminous band was the most conspicuous feature and its variations were very notable It drifted westwards, and in its transit passed over numbers of the stars, which, however, remained distinctly visible in many cases

THE CATANIA ASTROGRAPHIC CATALOGUE —The Catania Observatory undertook the zone between North Decl 46° and 55° in the Astrographic Catalogue It has had many difficulties to surmount through deaths of directors and shortage of funds, but is now issuing instalments of the Catalogue at short intervals under the direction of Prof G A Favaro The two latest instalments (vol 7, part 2, decl 52° to 54°, R A 3^h to 6^h, and vol 8, part 2, decl 53° to 55°, R A 3^h to 6^h) have lately been issued, it will be seen that decl 53° to 54° is common to both volumes The catalogue gives both the rectangular co ordinates and the R.A and Decl for 1900 0 for every star Most of the observatories limit themselves to rectangular co-ordinates, but Catania having once embarked on the more ambitious programme is unwilling to relinquish it It has of course many conveniences; the separate determinations for each star are immediately comparable without any reduction, The faintest magnitude included is 12 0

Research Items

The Teeth of Aboriginal Californians.—Dr. R. W. Leigh has made a study of pathological conditions in the teeth of three hundred crania of Californian Indians in the University of California Museum of Anthropology, which is published as No. 10 of Mem. 23 of the University's *Publications in American Archæology and Ethnology*. The specimens were derived from pre- or early post-conquest times when food habits had not been materially affected by Caucasian contact. Although food varied according to area, acorns and small seed food constituted a larger part of the diet than any other food. The grinding process for acorns, seeds, etc., was universal, and apparently this had deleteriously affected the teeth. The habitual eating of tobacco, especially when mixed with lime and mussel shells, and its use as an emetic, also affected the teeth. Other causes affecting the teeth were leaching of food with sand and cooking with hot stones. Much abrasive material was thus introduced into the mouth, and attrition with its sequelæ, is the conspicuous dental lesion in the majority. Seventy per cent of persons more than forty years of age had the pulp of one or more teeth exposed. Dental caries occurred in 25 per cent, though specimens from the shell mounds showed the low rate of 12 per cent. As a result of pulp exposure and necrosis, 52 per cent showed dissolution of continuity of bone surrounding the apices of the teeth—a result of attrition. Few teeth were lost before middle life—only ten dying at less than forty years of age had lost any teeth and most cases were well over fifty years. More superior than inferior teeth were lost.

Wooden Dolls from West Africa.—In *Man* for February, in the course of notes on the Wamakonde of Portuguese West Africa, Mr. H. D. Collings describes some remarkable little dolls of wood. The Makonde are very clever wood carvers, and these dolls are among the best things they made. They range in height from one to two feet. Their use is unknown, but coast natives state they were used in dances. They are carved in a soft white wood with a large central hole which is filled with pith. The wood is worked when green. Of two figures which are illustrated, one about 16 inches in height represents a woman. The upper lip is distended by the lip ornament, an ebony ring, and the face is covered by the usual tribal marks. The front teeth are pointed as are the teeth of the Makonde—a tribal mark. Real human hair had been driven into the head by a screwdriver like implement. A small piece of wood has been left to join the left hand to the body, a peculiarity noted in nearly every specimen. The male figure has no tribal marks and the hand is not connected with the body. This figure is stained red with some vegetable substance, the eyes being left white. The models stand upright alone when placed on their feet. They are not common, and few natives know how to carve them. The smoking pipes of this people are also of some interest. They are of the water container type, the container being a young coconut shell which is fitted with two bamboos, one of which has a movable pottery bowl. In a more elaborate form which is described, a curved central strengthening piece of wood is carved with decorative designs very similar to the tribal marks.

Nesting Habits of Oropendolas.—The oropendolas build long pendant nests in colonies, and although they are familiar enough in tropical America, no connected study of their habits has been made. Frank M. Chapman has repaired this omission by an intensive study of the oropendolas (*Zarhynchus wagleri*) of Barro Colorado Island (*Bull. Amer. Mus. Nat. Hist.*, vol. 58, 1928). In the nesting colonies, which set to work very regularly about the first week in January, females outnumber males by about six to one, and yet it would appear that each male has only one mate—at a time—and that in view of the abundance of choice there is no marked display of sexual jealousy. The males take no part in the selection of the site, in the gathering of building material, the construction of the nest, the incubation of the eggs, or the feeding of the young. But they guard the females from the attacks of hawks during nest building and generally act as watchmen. The long swinging nest hangs from the upper branches of a tree, and the building of the bag, woven of tendrils, fine strips of bark, and plant fibres, with its contained nest proper occupies one month. The male never enters the nest but the female sleeps there, and lays two eggs which hatch after an incubation period of 17 days. A month later the young leave the nest. There is no attempt at concealment either in the position of the nest or in the bright colours of the birds themselves. Their safety depends on a constant vigilance and on a spontaneous dive headlong into the dense vegetation which is never far distant, when the alarm note is sounded.

New Zealand Fishes.—In a paper entitled "Studies in New Zealand Fishes" (*Proceedings of the New Zealand Institute*, vol. 59, Part 2, 1928), Mr. L. T. Griffin, assistant curator of the Auckland Museum describes several little known fishes and two new species. These include a large eel, *Gymnothorax nubilis*, the only specimen so far recorded from New Zealand previously known from Norfolk Island and the Indian Ocean and Archipelago. This individual measures 640 mm. in length. *Seriolella amplus* n. sp. is interesting as it apparently does not vary as do the other species of the genus. It is a fine fish and very plentiful, which makes it all the more curious that it has not been described before. The mackerel described, *Scomber australasicus*, is said to be very common in deep water beyond the Hauraki Gulf, moving about the coast in large shoals, and is also common in Australian seas. The specimen of the striped angler, *Antennarius striatus*—a most grotesque creature with two pyramidal humps on its head and a lure resembling a three fronded piece of alga—was found hiding in a bunch of seaweed. Most of the species of this genus live in seaweed floating in tropical seas, and by filling the spacious stomach with air are able to keep near the surface of the water. In this way they can live in the open sea as well as near the coast, but they are very poor swimmers and drift with the currents into various places. This paper is exceptionally well illustrated by good original drawings.

The Anatomy and Habits of the Lophogastrid Crustacea.—The Lophogastrida, including the genera *Lophogaster* and *Gnathophausia*, have long been regarded as among the most primitive Mysidacea, and Miss Manton (*Trans. Roy. Soc. Edin.*, vol. 56, pt. 1, No. 5, 1928) has examined specimens of these genera in the light of the recent work on the feeding mechanisms of the Malacostraca which we owe to Miss Manton herself and to Prof. H. G. Cannon. Miss Manton finds that *Gnathophausia* has mouth parts of the typical filtratory form, and must, therefore, be at least a partial filter feeder. The mechanism is, however, more primitive than in any other living Malacostraca by reason of the absence of an auxiliary food current

created by the thoracic exopodites Locomotion is effected by the abdominal pleopods entirely, and the thoracic exopodites mainly cause currents of water bathing the gills *Lophogaster*, on the other hand, is a bottom living form, incapable of filter feeding The mouth parts are modified for feeding on large food masses, and the modifications resemble those found in the higher Peracarida which have given up filter feeding The mandibles of the Lophogastrida compared with those of other Malacostraca appear to be primitive in form, and to show the origin of the *lacinia mobilis* The author has also investigated the segmentation of the abdomen and the muscular system of the terminal 'segment' in *Lophogaster* and *Gnathophausia*, and finds that the groove across the last 'segment' of the abdomen in the Lophogastrida represents the junction between the incompletely fused sixth and seventh segments In a previous paper the author has shown that the last abdominal segment in the adult of *Hemimysis* is formed by the complete fusion of the separate sixth and seventh segments present in the embryo In the Lophogastrida the fusion between these segments is therefore incomplete This interesting observation brings the segmentation of the Eumalacostraca into line with that of the Leptostraca (*Nebalia*) where a completely separated but limbless seventh segment in the abdomen is a feature of the adult condition Miss Manton concludes that the Lophogastrida are the most primitive living members of the Malacostraca

PHILIPPINE WOODS —In the May number of the *Philippine Journal of Science* Mr Jose C Espinosa of the Bureau of Science, Manila discusses "Strength Properties in relation to specific gravity of Philippine Woods" The paper, which is illustrated by five text figures, is of a technical nature and designed for research workers in this branch of investigation The strength properties of wood have a certain definite relation with its density or specific gravity Newman and Wilson have carried out an analysis of 200,000 tests at Madison for American timbers and L G den Berger in the Dutch East Indies has worked on teak Mr Espinosa has carried out about 45,000 tests for some of the more valuable Philippine timbers and presents their relationships both in graphical and in equation form

GLACIAL DRIFTS AND ERRATICS —The Yorkshire Geological Society and Sir Sidney Harmer have laid British geologists under a debt of gratitude for making possible the posthumous publication of a paper on "The Distribution of Erratics and Drifts" in England and Wales, accompanied by a beautifully layer coloured contoured map on which the distribution is effectively displayed, both paper and maps being the work of the late F W Harmer (*Proc Yorks Geol Soc*, November 1928, pp 79 150, and sold separately by John Bartholomew & Son, Ltd, Edinburgh 10*s* with folded map, or 11*s* with unfolded map on a roll) Mr Harmer had a personal familiarity with the drift deposits extending over some sixty years, which was unrivalled in extent and achievement, and the invaluable result of this long service to geology is the first detailed mapping of erratics in England and Wales The map itself is on the 1/*M* scale and measures about 20 in × 25 in, it includes southern Scotland south of Peebles and Lanark The contour interval is 100 ft up to 600 ft, thereafter the contoured levels are 1000 ft, 1500 ft, and 2000 ft By the use of an ingenious system of twelve distinctive symbols printed in heavier colours than those used for the contour intervals, the following varieties of drifts and erratics are recorded North Sea, Chalky Boulder Clay (chalk matrix), Chalky Boulder clay, (Jurassic matrix), Pennine (Carboniferous), Pennine (Silurian), Welsh, Lake District, Cheviot and Galloway, Bunter Pebble, Charnwood, Eocene of Herts, and Neocomian (erratics of large size) The map is a masterpiece of clarity and accurate registration The very high cost of reproduction has been made possible by the generosity of Sir Sidney Harmer and his co trustees under his father's will It will interest many readers to know that the original map has been presented to the Geological Survey and Museum in Jermyn Street

IRRIGATION IN INDIA —The Triennial Review of Irrigation in India of which the issue for 1924–27 has now been published by the Government of India contains much useful statistical information It recounts the progress of irrigation in the various provinces of British India and gives financial statistics for all the irrigation works The irrigated area is now a little more than twenty eight million acres In productive irrigation works every province shows an improvement compared with the previous triennium The irrigated area is as much as 88 per cent of the total cropped area in Sind, and averages for the whole of British India 12 8 per cent being naturally very low in Bengal, Bombay Orissa and the Central Provinces Not the least valuable part of the pamphlet is the account given of the various irrigation projects in each province

THE ORIGIN OF MAGNETISM The issue of the *Physikalische Zeitschrift* for Dec 15 contains an account by Dr O V Auwers of recent work on the question why certain substances are magnetic and others not According to Heisenberg each atom of a magnetic element must have at least 8 neighbouring atoms of the space lattice at equal distances from it According to the author an examination of magnetic elements furnishes no direct contradiction to this law But when magnetic α iron passes into non magnetic β iron or magnetic α nickel into non magnetic β nickel between 700 and 800 C there is no distinct change in the space lattice of either Alloys of two of the magnetic elements iron nickel, and cobalt are sometimes non magnetic although the space lattice suggests by Heisenberg's rule that they should be magnetic On the other hand iron pyrites and magnetite are both magnetic, although they do not conform to the rule At present therefore we appear to have no satisfactory explanation of the origin of magnetism

ABSORPTION OF PENETRATING RADIATION —The only method yet devised for analysing the spectrum of the cosmic rays is to find by experiment how their intensity falls off in their passage through matter and then to calculate the wave lengths which correspond to the observed coefficients of absorption by making use of some specific theory of the interaction between radiation and electrons The two principal absorption formulæ which have been employed are those associated with the names of Prof A H Compton and of Dr Dirac, but recently a relation with a better theoretical basis has been proposed by Klein and Nishina (see NATURE vol 122, p 398) In interpreting the absorption curves it is also necessary to consider precisely what is registered by a γ ray electroscope and a new analysis of the problem by L H Gray (*Proceedings of the Royal Society* vol 122, p 647, Feb 4) in which all of these factors have been taken into account, has shown that the wave lengths which had previously been accepted as correct are probably in need of considerable revision The formula of Klein and Nishina is not only the most satisfactory of the three theoretically, but it also agrees best with the somewhat meagre data which are available concerning the absorption of γ rays of known frequency If this is adopted, the principal rays in the spectrum of the

penetrating radiation work out to be of even shorter wave length than Prof Millikan and Dr Cameron had supposed, and have quanta of 90, 360, and 920 millions of electron volts respectively The last number corresponds to the annihilation of a mass almost exactly equal to that of a proton, whereas Prof Millikan and Dr Cameron had suggested that it arose from the catastrophic condensation of a number of hydrogen nuclei and electrons to form the nucleus of an atom of silicon, magnesium, or aluminium

RADIO ACOUSTIC POSITION FINDING —In order to construct the nautical charts used in the naviga tion of ships it is essential that accurate hydro graphic surveys be periodically made In this way sunken rocks, reefs, and wreckage are accurately charted One of the methods, developed during the War, of locating objects is to utilise the difference be tween the speed of radio waves and under water sound transmission Many difficulties had to be overcome, such as the failure of sound to carry under certain con ditions and the interference at shore stations The U S Coast and Geodetic Survey has published a useful booklet (*Special Publication* No 146, price 20 cents) giving a clear and full account of the method and details of the instruments used by the survey ships operating on the Pacific Coast of the United States Radio acoustic control has been used for the last four years and has proved of great value It can be used regularly up to a distance of 70 miles from the shore, but in special cases it has been used at 200 miles It is independent of fog, but during storms the noise of the waves breaking on the beach sometimes causes difficulty The under water sound is obtained by exploding a bomb, and the noise is picked up by a suitably placed receiver connected through an ampli fier to a relay, both the sound and the radio signals being amplified A chronograph with two pens marks the instants when the sound and the radio signals are received The time taken by the sound travelling through the water to two stations on the coast is ob served Hence since the velocity of sound in sea water of known salinity and at known temperature is given by tables their distances can be found and the ship's position obtained Sometimes the noise made by fishing boats anchored near the sunk hydro phone makes it impossible to distinguish which are the bomb noises The only remedy is to remove the boats Another source of trouble was traced to fish bumping against the hydrophone box and to crabs climbing over it

CHEMICAL EFFECTS OF CATHODE RAYS —The *Journal of the American Chemical Society* for December contains three papers on the chemical effects of cathode rays The first two papers, by A L Marshall, deal with the formation of ozone and the union of hydrogen and oxygen effected by cathode rays from a tube operated at 200 kv and 0 001 amp Cathode rays bring about the ozonisation of oxygen and also the decomposition of ozone, the reaction taking place entirely in the gas phase A steady state is reached corresponding with a concentration of 1 molecule of ozone to 1700 of oxygen The silent discharge pro duces a concentration of 1 in 12, but has a much smaller decomposing effect than the cathode rays The reaction is uninfluenced by the nature of the walls of the containing vessel In the reaction between hydrogen and oxygen brought about by the rays, it was found that the primary products are hydrogen peroxide, water vapour, and ozone The rate of formation of the peroxide is independent of concentration, whereas the rates of formation of water vapour and ozone, which parallel one another, are both changed by variations in concentration It is suggested that both water vapour and ozone are produced by the same primary mechanism The third paper, by W F Busse and F Daniels, is con cerned with the chemical effects of the rays on oxygen, air, nitric oxide, and carbon dioxide These effects were expressed as the ratio of molecules produced per electron crossing the cathode ray tube, and were nitric oxide decomposition 230, ozone from oxygen 100, ozone from air 44, nitric oxide from air 14, carbon dioxide decomposition 3 The results described in all three investigations show that there is a close similarity in the chemical behaviour of cathode rays and α particles

ATOMIC WEIGHT REPORTS —Since the International Committee on Atomic Weights has not provided a table since 1921, the Report and Table of Atomic Weights prepared by the Sub Committee of the Chemical Society (*Journal of the Chemical Society*, pp 216 219, 1929) and those prepared by the German Atomic Weight Commission (*Berichte*, vol 62 pp 1 23) afford an interesting basis for comparison It is satis factory to note that of the eighty four elements tabu lated, only fourteen differ in more than one unit of the last significant figure in the weights assigned to them by the two tables Of these, the more important are carbon, sodium phosphorus, and arsenic, for which the English Sub Committee adopt the values 12 003_6, 23 000, 30 98_2, and 74 93_4 respectively (last figures are uncertain), on the basis of the results obtained by Aston with the mass spectrograph, the German values are 12 000, 22 997, 31 02, and 74 96 respectively For magnesium (24 30, 24 32—the English value is given first in each instance), calcium (40 09, 40 07), chromium (52 04, 52 01), manganese (54 95 54 93), niobium (93 3 93 5) gadolinium (157 0 157 3), and tantalum (181 3, 181 5), the English value is that recalculated by F W Clarke in 1919 since when there have been no new determinations There re main silicon (28 08, 28 06), copper (63 55, 63 57), and thorium (232 15, 232 12), with which there is no im mediately obvious reason for the slight differences Interesting features are, in the German Report, the provisional atomic weight 188 71 for the newly dis covered element rhenium (Re), which has been investi gated by Walter and Ida Noddack, and in the English report the arrangement, for the first time in an annual atomic weight table, of the elements in the order of their atomic numbers

FLAMES IN NITROUS OXIDE —The normal infra red spectrum derived from a flame is usually that of the products of reaction and not of the reacting gases This may arise from the fact that in most cases the supporter of combustion is oxygen or air, which are without characteristic infra red spectra In the *Journal of the Chemical Society* for January, Bailey and Lih describe experiments on the emission spectra of gases burning in nitrous oxide In the case of carbon monoxide and coal gas the anticipated spectra of water vapour and carbon dioxide were found, but a different result was obtained with hydrogen The flame of a mixture of this gas with nitrous oxide is very complex and consists of at least five zones, but the normal type of spectrum due to water vapour is shown When, however, a hydrogen jet is burned in nitrous oxide, a new spectrum appears, some bands of which appear to correspond with known absorption bands of nitrous oxide This new spectrum is not exhibited by carbon monoxide or coal gas in either mode of burning, and is probably due to some form of stimulation by burning hydrogen molecules It does not appear in the coal gas flame and is then probably inhibited by the carbon monoxide present Hence the stimulation is probably not merely thermal

British and Foreign Ammeters and Voltmeters

AT all electric generating and distributing stations large numbers of ammeters and voltmeters are fixed on the switchboards so that the attendants can see at a glance how the various electrical machines are working The manufacture of these instruments is quite an important industry, and we are glad that the manufacturers in Great Britain are thoroughly aware of the necessity of continually improving the design and accuracy of their instruments in order to meet foreign competition One sometimes hears from an engineer that a particular foreign instrument maker makes the best instruments, but there is no general agreement as to which foreign firm makes the 'best,' or in what respect these instruments are better than those made in Great Britain An investigation was therefore initiated by some of the members of the British Scientific Instrument Research Association to find out whether there was any foundation for these reports It was thought also that a careful comparison of the types of instruments made in America, Europe, and Great Britain would be of value as it might suggest to makers improvements in the design of their instruments

To bring the inquiry within manageable limits, it was decided to restrict the investigation at first to permanent magnet moving coil instruments and we have received a synopsis of the detailed report circulated to members of the Research Association For obvious reasons the names of the manufacturers are not mentioned, but the instruments are classified under the headings of British and foreign and a critical and impartial account is given of their design and performance

The manufacture of these instruments has lasted over so many years that the general lines of their design have become almost universal To obtain certain characteristics, however, different methods are adopted, and it is necessary to make compromises at almost every point in their manufacture, the instrument being judged on the general 'balance' obtained Users of instruments have generally definite preferences due to a liking for some particular detail in the design Not infrequently these preferences have no specific foundation and are merely personal

The instruments tested for the Association were 'dial type' switchboard ammeters and voltmeters varying from six to eight inches in diameter They were examined for rapidity of indication, accuracy, effect of temperature, internal construction, nature of the springs and of the magnetic system, appearance, and kind of pointers and dials used

In some of the instruments examined the damping was much too small When switched into the circuit the pointer moved over the scale in its first swing and struck violently against the stop at the upper end of the scale In some cases, also, there was a tendency for the pointer to stick at the upper end of the scale In other cases the pointer oscillated for some time before coming to rest The conclusion is arrived at that in the best instruments the damping should be almost but not quite critical, that is, that the pointer should swing slightly beyond its final position but return rapidly to it

Of the instruments examined, 60 per cent were accurate to within 1 per cent, 30 per cent had errors between 1 and 2 per cent, 8 per cent had errors between 2 and 3 per cent, and one instrument had an error of more than 9 per cent The general level of the accuracy of the British instruments was at least as high as that of the foreign instruments

The instruments were affected in very varying degrees by temperature Some of them were specially compensated for temperature In one of the British instruments the compensation was practically perfect from 10° to 50° C, the sensitivity of the instrument being constant to within one or two parts in one thousand over this range It appears that compensation for temperature can be provided to a satisfactory extent by a proper choice of the materials used in the moving coil circuit, control springs, shunt, etc The arrangements for zero adjustment were very varied In one case it was necessary to open the front of the instrument case to make the adjustment but in another the arrangement was very neat and efficient

The practice of fitting resilient supports to the jewels is to be commended, as it affords considerable protection against the risk of damage due to vibration or mechanical shock The instruments of two British manufacturers who follow this practice have a distinct superiority in this respect over all the others Some of the manufacturers use copper wire for their coils and others aluminium The use of aluminium has certain advantages, but it is difficult to solder Phosphor bronze springs were used by all the manufacturers for their instruments Only in two of them was the position of the zero reading of the pointer found unchanged after they had been in circuit for seventy two hours The pointers came back to their original zero positions after intervals varying from a few minutes to twenty four hours It was found that instruments with large air gaps in their magnetic circuits were not necessarily inferior to those having smaller air gaps It is necessary however, to maintain a proper relation between the magnetomotive force of the magnet and the reluctance of the magnetic circuit

So far as the external appearance of the instruments is concerned, it is best that only the scale and the pointer should attract the eye Full white dials and bright lacquered brass cases are not desirable It was found that certain scales were easier to read than others, and this was attributed to a better balance between the thickness of the gradations and their height The instruments were not tested to determine the extent to which their indications were affected by external magnetic fields We think that this was a pity, as many switchboard instruments are seriously affected in this way It is stated however, that inspection of the instruments showed that some would be affected much more than others

In conclusion, the report says that the best of the instruments examined, both British and foreign, were well suited for the purpose for which they were designed Two pairs of instruments of British manufacture were open to criticism in respect of certain details of construction, and two pairs of foreign instruments were distinctly inferior both in design and construction None of the instruments showed an outstanding superiority over all the others in every particular If the instruments are placed in order of merit as assessed on some particular criterion of excellence, the instrument placed first would in many cases be a British one Certain of the British instruments examined would occupy high positions whatever criterion were chosen The consistently high positions occupied by certain British instruments in the tests described above leads to the conclusion that the best known British instruments of the kind examined are quite equal to the best known corresponding instruments of foreign origin

The Timber Resources of the British Empire

ACTING under a resolution of the Imperial Conference which sat in London in 1926, an Imperial Economic Committee was appointed consisting of nominees of Great Britain, the Dominions, India, and the Colonies and Protectorates. The Imperial Conference directed the Economic Committee to prepare for the consideration of Government a list of raw materials suitable for inquiry on the lines of the Committee's reports dealing with foodstuffs. In 1927 the Governments of the Empire agreed that the Committee should prepare such a report on timber. This report (*Rep. of Imp. Econom. Committee*.—Tenth Report.—Timber. London: H.M. Stationery Office, 1928) has been recently published. It is based on the examination of a number of witnesses representing producing, marketing, and manufacturing interests, and on the expressed opinions of experienced officials and scientific workers.

The authors of the report give their reasons for confining themselves to timber and omitting other forest produce in the following: "We have excluded from our enquiry the wide range of articles frequently described as 'minor forest produce,' including grasses, canes, gums, and tanning materials. We have only referred to the imports into the United Kingdom of manufactured wood, of wood pulp and of cellulose for the purpose of indicating the total demand made by the United Kingdom on the sources of wood supplies. We took some evidence on the import trade in manufactured wood, but found that this raised very large issues, an examination of which would have prevented the production of this report in time for the forthcoming Forestry Conference. We therefore deemed it advisable to confine this Report to the raw material—timber. The timber trade is a very important one, and the Empire resources are extensive and varied."

One of the chief points, perhaps of equal interest and importance, which emerges from the evidence taken by the Committee, is the difference of opinion on the subject of world timber supplies of softwoods which exists between the members of the timber trade and forest authorities 'all the world over,' as the Committee expresses it—although it is doubtful whether there is such a universal consensus of opinion as this statement would appear to indicate. However, the forest authorities are said to regard the world supplies of soft woods with anxiety, whereas the authors state: "We must, however, record the fact that in the course of our enquiry we have not found this feeling of apprehension shared generally by the members of the timber trade in the United Kingdom. Adequate supplies have always been readily available in the past, and it is possible that the trade has been lulled into a feeling of security for the future which the world position may not warrant. The commercial point of view is that a scarcity of supplies will adjust itself by an increase of prices which will bring within an economic radius fresh forest areas hitherto untouched." Many forest officers would say that the local timber traders have as good knowledge of the local forests' resources as they have themselves. It is at least open to doubt whether the statement in the report that "the outlook is more fully realised by those concerned with organised forest management and conservation" can be accepted without considerable reservations.

Although the examination of forest resources does not fall within the purview of the Committee in the present report, the necessity for systematic investigation of the rate at which the softwood resources of the world are being depleted is strongly urged. It is well known that Canada contains practically the only supply in the British Empire of such materials, and probably the estimates of existing amounts are fairly trustworthy. The remaining resources are chiefly in European countries, and "systematic investigation" into their rate of depletion is not a practical possibility. We have to rely upon published figures—trade and otherwise, and on reports and information with which the officials of these countries courteously supply us.

The second point in the report is of Empire importance, and in it is embodied the entire value of statistics on Empire resources. The authors write: "If the interest of the timber trade and of the general public is to be enlisted for the conservation and development of the Empire forest resources and the lesser known varieties of Empire grown timber are to secure wider utilisation, statements regarding the world and Empire position must be supported by statistics based on precise knowledge and not on information of a general character." This goes to the root of the whole matter.

For the first British Empire Forestry Conference, held in London in 1920, a tabular form was drawn up, it is believed in London, and sent to forest authorities in countries of the British Empire asking for estimates of the total forest resources of these regions, distinguishing areas containing merchantable timber (exploitable forests) from non-merchantable. Some of the forest authorities produced figures for which they accepted no responsibility; others refrained. In Canada, at the Conference held in 1923, the same request was put forward, and in the report here under review the authors state: "Thus it is anticipated that in the autumn of the current year [*i.e.* after the meeting of the Empire Forest Conference in Australia] information on the timber resources of the Empire will be forthcoming more complete than any at present available." This latter is a possibility. But the statistics 'will not be based on precise knowledge,' which is what the Economic Committee rightly demands. How could they be? When a conservator of forests, in charge of one of the Empire provinces containing extensive tropical and sub-tropical forests, receives the form alluded to above, he sends copies to his several divisional officers. These men may have charge of an area of anything from 500 to 2000 sq. miles of forest (or more), in many cases much of it unknown and unexplored. They have a staff small in size and partially trained. How are they to produce any figures of stocking, either in proportion of species or volume per unit of area? Even the map areas of the forests are perhaps only rough ones. To anyone who has held charge of similar areas the possibility of obtaining any figures but those based on guess work will be perfectly obvious. Yet a large proportion of the tropical and sub-tropical forests of the British Empire are in this position. Very much stronger trained staffs and opening up of the forests will be necessary before the value of the returns on the timber resources of the Empire are based on "precise knowledge" as against "information of a general character." Outside the Empire there are extensive areas of tropical and subtropical forest (in South America, for example) which are as yet under no true forestry management at all.

We are in full agreement with the writers of the report "that it may be found necessary to make arrangements for the systematic collection and revision of World and Empire consumption in relation to supplies." But the primary basis for those preparing reports in London and suggesting work to be carried out, at any rate where forests and forestry are in question, is to remember that the unit of area is the square mile, the type of forest tropical or sub-tropical, the vegetation often dense and difficult to get through,

whilst the topography of the countryside often offers considerable obstacles to easy or rapid travelling The young British forest officer minds none of those things But knowledge, a trained staff, plenty of time (which entails much larger staffs), and an adequate equipment are required if the figures obtained for the total forest resources of the Empire (even for merchantable timber) are to be of a practical value We find no reference to this part of the problem in the report under review

The suggestion for co operation amongst the owners of woods in Great Britain for improving their woodlands and in marketing the produce are to the point also on the important subject of the introduction of new Empire hardwoods on to the home markets In this latter matter the forest officer is practically powerless It is a question for the timber merchant, and as the writers of the report rightly say, the introduction of new timbers "involves risk and expense which exporters with or without Government aid, must be prepared to undertake", and they add "We advocate a policy of restraint in regard to the number of varieties of new Empire timbers which are concurrently introduced into the British market"

This report is a valuable piece of work covers a wide range of outlook in the timber problems of the British Empire and its perusal may be strongly recommended to all who are in any way interested in timber supplies

The Four Component System in Peace and War

DR F A FREETH, of Imperial Chemical Industries Ltd honorary lecturer in the theory and practice of heterogeneous equilibria at University College, London, gave his inaugural address on Friday, Mar 1 on "The Four Component System in Peace and War"

The particular type of four component system with which Dr Freeth dealt is known as the reciprocal salt pair, or as a double decomposition One of the latest and best known examples of this is the conversion saltpetre process, whereby potassium chloride and sodium nitrate are converted into potassium nitrate and sodium chloride The subject was developed along the lines of Meyerhoffer one of the pioneers of this field who published his paper about thirty years ago but the method of representation used to explain the original arguments was that developed by Prof Janecke of the Technical High School Hanover

The method of representation takes the form of a cube the base of which represents all the possible mixtures of the salts whilst water is plotted vertically Considering the base of such a cube only, that is to say, the relative proportions of the salts, such base can be considered as being divided into four areas, each of which represents saturation with respect to one of the four salts under consideration If by any means a solution can be obtained within an area representing saturation with respect to a particular salt, then generally speaking it is possible to obtain that salt in a pure condition

The famous reciprocal salt pairs of commerce were then considered, particular attention being paid to the ammonia soda process which was developed in Great Britain by the late Dr Ludwig Mond Several other well known working processes were also discussed, notably the caustification of sodium carbonate by lime giving caustic soda All these old commercial processes were developed empirically, and it is generally found that current practice corresponds very closely with the optimum conditions predicted by a stringent theoretical treatment

Reactions of this character played a very important part in the War Fixed nitrogen is essential for modern explosives, both for propellants and for the high explosives used for bursting charges in shells Until the War, the main source of fixed nitrogen was Chile nitre, treatment of this nitre with sulphuric acid yields nitric acid, which can be converted into high explosives like tri nitro toluene, propellants such as cordite, and by neutralisation with ammonia can be made to yield ammonium nitrate Germany obviously could not depend indefinitely on the Chile supplies, so the Haber and the Ostwald processes were developed The Haber process makes ammonia, using coke, air, and water as raw materials, the Ostwald process, by burning ammonia with a limited quantity of oxygen, converts it into nitric acid After these processes were once developed on a sufficiently large scale Germany was automatically independent of any outside supplies of fixed nitrogen Both processes, more especially the Haber process required very considerable advances in technique

On the outbreak of war in 1914 it soon became manifest that immense supplies of fixed nitrogen would be required by Great Britain Even assuming that the productive capacity making nitric acid on the old lines would have been sufficient there was a shortage of toluene for the necessary quantity of T N T had that explosive been exclusively used It was speedily discovered that T N T could be diluted with no less than four times its weight of ammonium nitrate without impairing the high explosive properties of the mixture The supply of ammonium nitrate, therefore became of vital importance Lord Moulton, the director of Explosive Supply, was faced with the following dilemma Should he attempt to erect Haber and Ostwald plants of the necessary size or should he attempt to make ammonium nitrate by double decomposition using Chile nitrate as his source of fixed nitrogen? He decided on the latter course for the very good reason that he considered the enormous calls on technical men of every kind rendered it almost out of the question to develop what was, in Great Britain, an entirely novel process

Three double decomposition processes were used in the War period, and nearly all of them had been considered as technically impossible after practical trial These processes were

(1) The ammonia soda reaction on sodium nitrate giving ammonium nitrate and sodium bicarbonate (2) Conversion of the waste calcium chloride of the ordinary ammonia soda process into calcium nitrate by double decomposition with sodium nitrate and the subsequent decomposition of the calcium nitrate with ammonium carbonate yielding ammonium nitrate and calcium carbonate (3) Double decomposition of sulphate of ammonia and sodium nitrate giving ammonium nitrate and sodium sulphate This latter process, after initial failure, afterwards became successful, it was worked on a very large scale in Great Britain and upon a still larger scale in the United States All these processes were developed both theoretically and practically in the research laboratories of Messrs Brunner Mond and Co, Ltd, of which Dr Freeth was the head

Finally, Dr Freeth paid tribute to the extraordinary help which those engaged in developing this process had received from theoretical work of the Dutch school, notably of Prof Schreinemakers in Leyden, while the germ of all the theories involved goes back to a most distinguished American mathematical philosopher—Willard Gibbs—probably one of the most detached men who ever lived

Fauna of the Paraguayan Chaco Swamps

A SERIES of papers on the fauna of the tropical swamps of the Paraguayan Chaco were read at the meeting of the Linnean Society on Jan 3 Messrs G S Carter and L C Beadle, in a preliminary paper, dealt with the relation of the fauna to the physico chemical conditions of the environment These swamps cover large areas of the plains to the west of the Paraguay River on the latitude of the southern tropic, those in the neighbourhood of the station of the South American Mission Society at Makthlawaiya (58° 19′ W, 23° 25′ S) were investigated They are shallow, frequently dry, and are filled with much aerial vegetation in all parts During eight months (October 1926–June 1927), observations were made at regular intervals of several characteristics of the water in the swamps The most striking observations were (1) The high temperature which the surface layers of the water were sometimes found to reach (42° C), (2) the large quantities of phosphates always present (up to 10 mgm per litre), (3) the low tension of dissolved oxygen, not more than 2 3 c c per litre in the surface layers, while below the upper 4 6 in there was scarcely ever more than 0 2 c c per litre during the hot weather This low oxygen content is believed to be due partly to the poverty of the aquatic flora, partly to the great activity of decay at the high temperature, and partly to the absence of convection currents caused by the cooling of the surface layers at night The behaviour and distribution of the fauna show that the shortage of dissolved oxygen in the water is the greatest bionomic factor

Dr R Gurney submitted a report on the Branchiopoda of the expedition Dr Carter's collections include five species of which three appear to be undescribed Four of them are Conchostraca, and include the remarkable *Cyclestheria hislopi*, which is found also in Africa, India, Ceylon, and Australia

Mr E Meyrick discussed the Microlepidoptera which were collected The nature of the region would probably not be very favourable to Microlepidoptera The number of species in identifiable condition is 32, of these, 2 genera and 22 species are described as new Of the remainder, 3 are horticultural pests introduced with their food plants, 1 a widely spread American insect, 2 are found also in the Argentine and 4 in the Amazon valley The new species are generally of Guiana and Amazon types

Messrs Carter and Beadle described their observations on the habits and development of *Lepidosiren paradoxa* The subsoil of clay, which occurs everywhere in the parts of the Paraguayan Chaco inhabited by this fish, preserves water in the burrow used in dry weather, thus keeping its skin moist Oxygen is normally absent from the water surrounding the nest of the *Lepidosiren*, and the manner in which the respiratory needs of the eggs and young larvæ are satisfied is discussed The normal rhythm of the contraction of the pigment cells of the skin of the larvæ at dusk and their expansion at dawn is preserved for some days when the larvæ are kept in the dark continuously

Dr J Stephenson dealt with the Oligochæta Oligochæta have been collected from the northern and more remote part of Paraguay only twice previously, and then only in small numbers, hence the present collection contains a large proportion of new species Limicoline forms are in the majority A considerable part of the interest of the present collection lies in considerations of geographical distribution

Dr W A Cunnington reported on the Argulidæ of the expedition, which belong to the genera *Dolops* and *Argulus* The two species of *Dolops*—*Dolops striata* (Bouvier) and *Dolops geayi* (Bouvier)—are of interest, as certain specimens are larger than any hitherto recorded The single species of *Argulus* appears to be new to science

Mr H W Parker discussed the Amphibia and Reptilia which were collected Dr Carter's collections contain two tadpoles and a half grown example of the frog *Ceratophrys lævis* (Budgett) The tadpoles, hitherto undescribed, have mouth parts of a kind unique amongst the Salientia, and, as their food is exactly similar to that of some other species of *Ceratophrys*, this suggests that *lævis* is not closely genetically related to the other members of the genus in which it is at present included

University and Educational Intelligence

CAMBRIDGE —D J Watson, Downing College, has been appointed to the Frank Smart University Studentship in Botany J C P Miller, Trinity College, has been elected to the Sheepshanks Exhibition

THE Chadwick Trustees invite applications from British subjects between twenty five and thirty years of age who are graduates of a British university or of equivalent standing, for two travelling scholarships of £400 each, to enable the holders to travel abroad during one year to study methods adopted in other countries for the prevention of disease and the improvement of the public health One scholarship will be for sanitary science and the other for municipal engineering Applications must be sent in before Mar 25, full particulars may be obtained from the Clerk of the Chadwick Trustees at 204 Abbey House, Westminster, London, S W 1

PARENT TEACHER associations have so grown, says the United States Bureau of Education in the November issue of *School Life*, that they have become one of the outstanding forces in American education Their members, numbering more than a million and a quarter, are organised under the guidance of the National Congress of Parents and Teachers, founded in 1897, for the promotion of a better understanding between parent and teacher with consequent co operation between home and school and appreciation on the part of all citizens of their responsibility to the younger generation The Congress executive operates, with the help of the teacher members, an ambitious scheme of adult education in which it has the powerful backing of the federal Bureau of Education and last September it promulgated a manifesto urging the supreme importance of universal education for parenthood In this document, which was published in the October issue of *School Life*, it calls upon universities and colleges to develop special courses in this subject in their teacher training, extension and correspondence study departments, exhorts public librarians to organise special facilities for its study, and State and city school officers to plan for bureaux of parent education The Bureau of Education is supporting this movement by publishing a series of nine articles by eminent authorities concerning parent teacher associations in their relation to the children and to the schools of elementary, secondary, and higher grade The first of these, on the Congress programme of parent education, appears in the November issue of *School Life* Others will deal with pre school education, the teacher, the parent and the curriculum, recreation as a necessary part of home life, parents and the sex question, parents and high-school students, parents in higher education, books, and parent education in the home

Calendar of Patent Records

March 11, 1835—A patent was granted to Robert Jupe, upholsterer of London, on Mar 11, 1835, for an improved expanding table in which the width was enlarged as well as the length, the principle being applicable to round or other shaped tables The table top was divided into a number of sections which could be caused by suitable mechanism to diverge from the common centre, the spaces thus formed being filled by inserting 'leaves'

March 12, 1839—The patent granted to Job Cutler of Birmingham for an improved method of constructing chains for suspension bridges and other purposes, and dated Mar 12, 1839, is one of the rare cases in which a caveat against the grant of a patent was entered at the Great Seal, the last stage at which a patent could be opposed The Attorney General, on the evidence of John Farey, reported against the grant, but the Lord Chancellor overruled the objection and sealed the patent as of the original date

March 13, 1561—The patent granted to Philip Cockeram and John Barnes in 1561 for the manufacture of saltpetre affords the first known instance of an official specification or written description in connexion with a patent for an invention, though the delivery of the description was not a condition of the grant It appears that Queen Elizabeth agreed to pay Gerrard Honricke, a German, the sum of £300 if he would teach certain of her subjects how to make saltpetre as it was made on the continent and would also give an account of the process in writing The 'specification' was duly delivered to the Secretary's office on or about Mar 13, 1561 The Queen thereupon granted a patent to Cockeram and Barnes for ten years, and transferred to them the obligation to pay Honricke the stipulated sum

March 14, 1769—On Mar 14, 1769, within a few weeks of James Watt's steam engine patent being sealed, a patent was granted to Francis Moore, draper, of London, which made Dr Small write to Watt "Moore has taken out a patent for moving wheel carriages by steam This comes of thy delays At this moment, how I could scold thee for negligence" Watt was not, however, perturbed by the information, and replied that Moore could not make a steam carriage without using his (Watt's) patent, and that if he did use it, Watt would easily be able to stop him No specification was enrolled with Moore's patent, and the only evidence of his improved carriage shows a horse drawn vehicle having very large diameter wheels

March 15, 1784—The argand burner, the first notable improvement on the primitive oil lamp, was invented by Amié Argand, a French chemist living in London, and patented by him in England on Mar 15, 1784 Argand was anticipated in France by Ambroise Lange, who had seen the invention in London and gave it to the Paris Academy as his own Later, the two joined forces, and a French patent was granted in the two names, but this with other similar privileges was suppressed by the Revolution and the invention thrown open to the public Argand's reason gave way under the series of misfortunes and he returned to England to devote the remainder of his life to an attempt to discover the elixir of life

March 16, 1744—A patent was granted to Samuel Sutton on Mar 16, 1744, for a method of extracting the foul air from the holds and living quarters of ships through pipes heated by the ordinary cooking and other furnaces of the ship Sutton himself tells that he experienced great difficulty in getting the invention adopted by the Admiralty, but eventually it was installed in a large number of H M ships

Societies and Academies

LONDON

Royal Meteorological Society, Feb 20—**L H G Dines** The Baker automatic release for dropping the meteorograph from a registering balloon at a predetermined height—**C K M Douglas** Some aspects of surfaces of discontinuity The more important pressure changes on weather maps are due mainly to large scale horizontal movements at levels round about the base of the stratosphere, considered in conjunction with movements at lower levels The changing pressure fields cause converging and diverging movements, which influence fronts and produce inversions where the air is subsiding—**E Kidson** and **H M Treloar** The rate of ascent of pilot balloons at Melbourne Atmospheric turbulence is the most important cause of departures from the normal rate of ascent The greater the turbulence the greater is the mean height The turbulence due to surface heating of the air is more effective than wind turbulence in increasing the rate of ascent in the lowest layers The heat turbulence is effective chiefly near the surface and in light winds The rate of ascent is less in stable than in unstable air under the same conditions as to turbulence

Physical Society, Feb 22—**L F Stanley** The construction and calibration of a sensitive form of Pirani gauge for the measurement of high vacua The gauge consists of a manometer and a compensator, the one identical with the other, placed in the opposite arms of a Callendar Griffiths bridge, each consists, essentially, of a loop of 10 cm of platinum wire of 0 001 inch diameter, together with a compensating loop of 2 cm of the same wire The symmetry of the circuit makes errors due to thermoelectric effects very small The gauge follows variations of pressure with considerable rapidity, and its range of measurement is from 2×10^{-3} mm to 4×10^{-6} mm approximately—**Charles H Lees** The free periods of a composite elastic column or composite stretched wire The free periods of the longitudinal oscillations are determined when both ends of the column are nodes when one is an antinode and when both are antinodes A graphical method of dealing with the problems is developed—**Allan Ferguson** and **J A Hakes** A capillary tube method for the simultaneous determination of surface tension and of density A capillary tube of radius r is immersed vertically to a depth h_1 in a liquid of density ρ_1 The pressure $g\rho h$ required to force the meniscus down to the lower end of the capillary and to hold it there is measured If h_1 and consequently h be varied, a plot of h against $(h_1 - r/3)$ gives a straight line, from slope and intercept of which the surface tension and the density of the liquid may be inferred

CAMBRIDGE

Philosophical Society, Jan 28—**Sir Ernest Rutherford** and **J Chadwick** Energy relations in artificial disintegration Experiments on the disintegration of aluminium indicate that the change of energy is not the same for each nucleus, but that it may vary by so much as 5×10^6 electron volts Hence, either the mass of the aluminium nucleus or that of the nucleus formed in the disintegration may vary by nearly 0 006 mass units—**R H Fowler** An analogy for beams of particles of a reciprocal optical theorem due to Helmholtz—**D R Hartree** The distribution of charge and current in an atom with several electrons obeying Dirac's equations The approximation is made that each electron can be treated as in a stationary state in the field of the nucleus and the

remaining elections, and further that this field is spherically symmetrical An exact formula for the magnetic moment corresponding to a solution of Dirac's equation in a central field is given, and leads to Landé's g formula when 'relativity effects' are neglected —**N Feather** and **R R Nimmo** The distribution of range of the α particles from radium C′ and thorium C″ Distribution curves relative to 2134 α particles from thorium C′ and 729 from radium C′ showed that many more had ranges between 6 cm and 8 cm of standard air than was expected, and that the excess of short range particles was much greater in the former case than in the latter, where the results agreed satisfactorily with those of Briggs, obtained by the magnetic deflexion method —**R M Gabriel** Some further results concerning the integrals of moduli of regular functions along curves of certain types

PARIS

Academy of Sciences, Jan 28 **V Grignard** and **Tchéoufaki** The α diacetylene hydrocarbons Hydrocarbons of the type RC≡C–C≡CR can be obtained in good yields by the action of iodine in ether solution upon alkyl magnesium compounds, provided that the conditions laid down are closely followed In the fatty series, dipentine, dihexine, and diheptine have been prepared by this method, and several aromatic hydrocarbons of the same type are also described Phenyltriacetylene, $C_6H_5-C\equiv C-C\equiv C-C\equiv CH$, has also been prepared and its properties are given —**Serge Bernstein** Orthogonal polynomials —**Auguste Lumière, Mme R H Grange**, and **R Malaval** The pH of arterial blood and of venous blood Measurements by the electrometric method give pH values of 7 85 for arterial blood and 7 50 for venous blood The main cause of the variations appears to be the amount of carbon dioxide present —Georges Birkhoff was elected *correspondant* for the Section of Geometry in the place of the late Ivar Fredholm, and Adrien de Gerlache *correspondant* for the Section of Geography and Navigation in the place of the late Sir Philip Watts —**Maurice Fréchet** The distance of two contingent variables —**Lucien Féraud** Bundles of conjugated networks **Frank Loebell** The generalisation of a theorem of H A Schwarz —**Nicolas Cioranesco** The problem of Dirichlet for systems of equations of the elliptic type and the extension of a functional relation of M Hadamard —**A Gay** The movement of a cylinder in a viscous fluid —**Jules Baillaud** The determination of the galactic pole from the data of the selected areas —**L d'Azambuja** The use of the spectro heliograph for the determination of the level of the vapours of the reversing layer or lower portion of the solar atmosphere —**H Pélabon** Rectification by purely metallic bad contacts A description of the phenomena observed using as rectifier two similar steel cylinders separated by a thin layer of lycopodium powder or cork dust —**Henri Gutton** The effect of a magnetic field on the resonance phenomena in ionised gases —**P Salet** The constancy of the velocity of light Arguments against the application of the ballistic theory to the explanation of the changes in the intensity of light in certain stars —**E Darmois** The rotatory power of the tartrates of certain organic bases contribution to the study of strong electrolytes —**A Smits** The allotropic modifications of phosphorus Remarks supplementing the author's communication of Nov 29 last, and criticism of the work of Nicolaïeff on the same subject —**W Swietoslawski** A boiling point apparatus designed for researches under high pressures A modification of an apparatus previously described capable of being used under pressures up to 25 atmospheres —**A Zmaczynski** A new modification of a boiling point apparatus used for high pressures —**M Prettre** and **P Laffitte** The temperature of ignition of combustible gaseous mixtures The results given in an earlier paper on the temperatures of ignition of mixtures of air and hydrogen are much lower than those given by other workers, and this is attributed to the lower initial pressure adopted The present paper gives the result of the influence of the preliminary vacuum on the temperature of ignition —**Mlle Germaine Marchal** The action of silica, alumina, and of kaolin on barium sulphate **Mlle Jeanne Lévy** and **A Tabart** The relative affinity capacities of various radicals on the course of the isomerisation of the trisubstituted ethylene oxides —**P Fallot** The relations of the sub Betic with the Betic in the Sierras Tercia and Espuña —**H Pollet** Atmospheric electricity in the course of the sand storms of the north of China The electric charge on each dust particle is of the order of 100 times the elementary charge of an ion —**P L Violle** and **A Giberton** The neutralisation of the oligodynamic power of copper by solutions of electrolytes Application to mineral waters —**Georges Truffaut** and **G Thurneyssen** The influence of artificial light on the growth of the higher plants A description of the lighting arrangements by means of which normal beans and strawberries have been produced The microscopic examination of the leaves of the strawberry plants cultivated in artificial light showed that they were normally provided with chlorophyll and that their palisade tissues exactly resembled the normal palisade tissue of plants raised in daylight —**Charles Pontillon** The existence of resins in *Sterigmatocystis nigra* **J Manquené** The alluvial formations of western Algeria after the inundations of 1927 —**Lucien Daniel** The accentuation and persistence of symbiotic adaptations in the Jerusalem artichoke grafted on the annual sunflower —**Mlle G Fuchs, J Régnier, D Santenoise**, and **P Vare** A thyroid hormone regulating the cerebral excitability —**Paul Wintrebert** The liquefaction of the internal sheath of the egg in the urodelan Amphibia —**René Fabre** and **Henri Simonnet** The comparative study of the value of the biological test and the physical test of irradiated ergosterol It appears to be premature to attribute to the biologically active product a definite absorption spectrum **R Fosse** and **A Brunel** A new ferment This ferment, named allantoinase is found in various leguminous seeds and is characterised by its power of hydrolysing allantoin to allantoic acid

ROME

Royal National Academy of the Lincei, Nov 11 —**T Levi-Civita** The motion of a body of variable mass —**G Fubini** Further considerations on the transformations of Laplace, Lévy, and Moutard for hypersurfaces —**G Abetti** Anomalies of gravity and deviations of the vertical determined by the De Filippi expedition in Central Asia (1913–14) The results obtained by this expedition, taken in conjunction with those of the Survey of India to the south of the Himalayas and those of the Russian Geodetic Service in Turkestan and Pamir, show that on these mountain chains the gravitation constant is usually in excess To the south and to the north it is, however, usually deficient, this being an indication of the probable equality of the conditions of compensation or non compensation in the Indo-Ganges plain and in the plains of Turkestan —**F Vercelli** Experimental considerations concerning certain geo electric methods —**L Rolla** and **L Mazza** Concerning thallium photoelectric cells The procedure recently described by Majorana and Todesco for the preparation of thallium photoelectric cells

was published by Rolla in 1927 and has been patented Such cells have been successfully used by the Italian military authorities —**G Ascoli** The singularity of the solution in Dirichlet's problem A sufficient condition, not of purely geometrical character, but of ready applicability, is given for the validity of the theorem of singularity of the solution in Dirichlet's problem —**F Sbrana** A remarkable group of functional operators Some of the essential results are given of the author's recent investigations on the calculus of functional operators $f(\Delta)$ with $\Delta = \frac{\partial}{\partial t}$ and t variable and real This method of calculus, known as operational or symbolic calculus, is finding increasing application in the solution of numerous mathematical physical problems of industrial importance or inherent to modern atomic physics —**G Aliprandi** Determination of the principal triplet (terna)—of Vitali—of a generic surface, considered as an autopolar terna of the geodetic cone —**A M Bedarida** The algebraic bodies of Galois – **G Scorza Dragoni** Concerning a differential equation — **M Lelli** Bernoulli's theorem for homogeneous viscous liquids —**R Calapso** A new transformation of isothermal surfaces —**E Čech** Observations on the quadrics of Darboux — **G Sannia** New definitions of the canonical pencil – **M Maggini** Interferometric measurement of the effective wave length of double stars and its variation with the zenithal distance The interferometer is able to replace not only the micrometer where this is ineffective, but also the diffraction grating in the measurement of wave length, and the photometer in the measurement of extinction – **E Adinolfi** The influence of X rays on the structural conditions of bismuth and tellurium (3) When absorbed by bismuth during its solidification, X rays modify the structure of the metal, which exhibits a diminished Hall's coefficient and becomes electropositive towards ordinary solidified bismuth Under similar treatment, tellurium also assumes a lower Hall's coefficient, but is rendered electronegative with respect to ordinary tellurium When solidified rapidly from the molten state, both of these elements increase in hardness and acquire an increased specific heat, the latter change occurring also in the case of solidification under the influence of X rays – **O Occhialini** Low voltage sparks as spectroscopic sources The procedure to be adopted to obtain these sparks, which are formed at a voltage of 220, is described —**P Agostini** Heats of formation of double cadmium potassium chlorides The heats of formation of the compounds, KCl, $CdCl_2$, and $4KCl, CdCl_2$, are found to be + 3 65 (3 73) Cal and + 0 989 Cal respectively —**G Bargellini and Lydia Monti** α Phenylcoumarins Various α phenylcoumarins have been prepared by the condensation of aromatic *o* hydroxyaldehydes with substituted phenylacetic acids —**G Bargellini and P Leone** 3 5 – Dichlorophenetidine The best conditions for preparing this compound by passing hydrogen chloride through an alcoholic solution of nitrosophenol (Jaeger's method) are described, together with several of its derivatives —**G A Barbieri** New method for the volumetric determination of cobalt In the green liquids resulting from the decomposition of cobaltinitrites by hot sodium hydrogen carbonate solution, all the nitro groups of the cobaltinitrous complex are present as alkali nitrate, whilst the tervalent cobalt forms part of a cobalticarbonic complex, to which the green colour is due If the liquid is introduced into permanganate solution acidified with sulphuric acid, the nitrous acid is oxidised quantitatively in the cold to nitric acid and the tervalent cobalt is reduced to the bivalent form, so that eleven equivalents of oxygen are consumed for each molecule of the original cobaltinitrite These reactions serve as a basis for the volumetric determination of cobaltinitrites and hence of the two elements which can be separated quantitatively as cobaltinitrites, namely, potassium and cobalt – **G R Levi** Further investigations on catalysis with metals of the platinum group The catalytic decomposition of hydrogen peroxide by platinum is greatly influenced by the presence of other metals of the group Iridium and, to a less extent, rhodium depress the catalysis, and palladium seems to act similarly to iridium Possibly owing to a positive influence of the metal and a negative influence of the oxide, ruthenium is almost without effect on the catalysis Although the catalytic formation of sulphur trioxide is influenced only slightly and negatively by osmium, the decomposition of the peroxide is very markedly increased in the presence of this metal **G Piccardi** The Röntgen levels of the rare earths and the derivations from Moseley's law – **A Barchiesi** Ponderal and histophysiological investigations on guinea pigs and rabbits subjected to injections of lipoid mixtures Injection of lipoid mixtures affects all the organs and tissues examined and modifies the whole organic metabolism The results seem to support Serono's assumption that, possibly owing to their special chemical character, lipoids form biological catalysts which induce many complex reactions —**G Brunelli** Biophysical nature of the pitted erosion of the arenaceous rocks of the Tyrrhenian coast Observations made at Capo Linaro show that the perforation of the rocks is due initially to small shells of *Littorina punctata* and *L neritoides*, which attack the rock at the points of least resistance Afterwards the action of the waves affects further destruction of the rock in the perforations initiated by the molluscs, so that the degradation is of mixed, biophysical character In certain cases *Patella* also plays a part in this phenomenon —**S Ranzi** Relations between organogenetic and histogenetic processes (Investigations on experimental morphology in the cephalopods) Considerations of phenomena relating to the development of the embryos of cephalopods indicate that, up to a certain point, histogenetic processes are independent of organogenetic processes This general principle is in complete accordance with many data obtained from experiments on the culture of the tissues of vertebrates, these showing that, for varying but usually short periods, the cells may retain their differentiation **Aldo Spirito** Regulative processes of the encephalic region of the embryos of *Anura* — **T Terni** Regeneration and super regeneration of tissue and of organ in the tail of adult urodeles

SYDNEY

Linnean Society of New South Wales, Nov 28 — **G D Osborne** (1) The Carboniferous rocks between Glennies Creek and Muscle Creek, Hunter River District, N S W Comprise representatives of the Burindi Series, a marine series of Lower Carboniferous age, and the Kuttung Series, of Middle to Upper Carboniferous age, the latter are at least 8000 feet in thickness, and have been subdivided into the volcanic and glacial stages The late Palæozoic diastrophism produced a basin structure and associated broad folding Connected with this movement there developed a series of normal faults, one of which—the Brushy Hill Fault—is of great importance Separating the Carboniferous rocks from the Permian strata is a great fault—the Hunter Overthrust, which is of later date than the normal faults —(2) The Carboniferous rocks of the Muswellbrook Scone District, with special reference to their structural relations This area described

is to the north of that discussed above and has similar stratigraphical and tectonic features In the north west is the important Wingen fault, which cuts across the Hunter Overthrust It then strikes into the Carboniferous rocks, and is marked by a wonderful *shatter zone, up to five chains in width* —**J R Malloch** Notes on Australian Diptera No 18 An alphabetical catalogue of genera and species of Tachinidæ —**A B Walkom** Notes on some additions to the *Glossopteris* flora in New South Wales Descriptions of (1) a collection of small *Glossopteris* leaves which belonged to the late John Mitchell, (2) two terminal shoots (from the collection of the Geological Survey of New South Wales) which may possibly represent part of the plant which bore *Glossopteris* fronds, and (3) a collection of seeds belonging to Mr T H Pincombe Some of the latter resemble very closely seeds described from Upper Carboniferous and Permian rocks in Europe —**Frank A Craft** The physiography of the Wollondilly River Basin To the west of the Illawarra coast there is an area of plateau country forming the basins of the Wollondilly and Nepean Rivers Behind the coastal scarp over an extensive area this plateau has an elevation of 2000 2500 feet and is drained by the Eastern Wollondilly system and the Lower Shoalhaven This gives place in the west to a higher tableland, which rises from south to north The plateau as a whole presents a mature surface which is being cut up by stream erosion most markedly in the north

VIENNA

Academy of Sciences, Nov 29 —**E Smreker** Anastomoses between the dentine channels and cement corpuscles in the chamois —**K Menger** The semi constancy of arc length —**O Wettstein** Amphibia and reptilia from Palestine and Syria —**F Heritsch** Corals from the Carboniferous of the Yeitsch in Upper Styria —**H Hahn** Continuous extension images —**F Dehmer** Irreducible continua —**J B Niederl** and **R Casty** New condensations of ketones with phenols (2) Further cresol phorones

Dec 6 —**L Moser** and **O Brandl** The determination and separation of rare metals from other metals (13) Re examination of the gravimetric analysis of vanadium and two new methods for its determination There are several lead vanadates, under certain conditions first lead hexa vanadate and then lead pyro vanadate is formed Vanadic acid can be completely precipitated with mercury nitrate again under certain conditions —**L Moser** and **F List** (14) Separation of beryllium from the metals of the alkaline earths and from the metals of the ammonium sulphide and arsenic groups One way is by forming difficultly soluble metal tannic acid adsorption complexes, the other by hydrolysis of the beryllium ion by ammonium nitrite and methyl alcohol —**E Späth** and **N Polgar** A synthesis of non hydrated iso quinoline derivatives —**A Skrabal** The varieties of unstable intermediate substances in chemical kinetics The intermediates during the main period of the reaction may be in equilibrium with the initial or with the final substances —**F Hölzl** Buff s substance and Bunsen's salt Salts of tetrabasic hexa cyano ferric acid with alcohol as base —**W L Ayres** Generalisations of Jordan's continua —**G Bergmann** Axioms in elementary geometry —**B Finzi** Ants from Greece and the Ægean islands —**D W Adensamer** and **F Käufel** Land and fresh water mollusca from Greece and the islands of the Ægean —**H Strouhal** Land isopods from Greece and the islands of the Ægean —**H Preisner** Rhyncota from Greece and the islands of the Ægean

Dec 13 —**V Pietschmann** New species of fish from the Pacific Ocean —**F M Exner** Dune studies in the Courland sandhill tongue, with an appendix on river meanders, clouds, and cyclones arising from friction eddies Sand waves are explained by horizontal eddies Small sand waves move rapidly, larger waves slowly —**F Sigmund** and **R Uchann** The *catalytic splitting off of alcohol from acetals* (*preparation of unsaturated ethers*) By using a clay catalyser at 200° 250°, nickel not essential —**C Doelter** Reactions with blue rock salt —**C Zawisch-Ossenitz** The development of the human femur —**W Figdor** Cone-shaped leaves and the asexual multiplication of *Bryophyllum proliferum* —**K Fritsch** Observations on flower visiting insects in Styria, 1908 —**G Ortner** and **G Stetter** The use of electronic valve amplifiers for counting corpuscular rays —**E Guth** Systems of linear partial differential equations of the first order, compatible with a given metric, especially Maxwell's equations and Dirac's equations for the electron —**F Urbach** The form of the absorption and emission *bands in solids* —**A Zinke, W Hirsch,** and **E Brozek** Researches on perylene and its derivatives (19) —**K Funke, F Kirchmayr,** and **H Wolf** Researches on perylene and its derivatives (20) —**A Pongratz** and **E Pochmüller** Researches on perylene and its derivatives (21)

Diary of Societies

FRIDAY, MARCH 8.

ANDERSONIAN CHEMICAL SOCIETY (at Royal Technical College, Glasgow), at 8 15 —W H Nuttall Rubber and its Commercial Applications

ROYAL SOCIETY OF ARTS (Indian Meeting), at 4 30 —W H Moreland The Indian Peasant in History

ROYAL ASTRONOMICAL SOCIETY, at 5 —Prof S. Chapman Solar Streams of Corpuscles their Geometry, Absorption of Light, and Penetration —N Goryatscheff Occultations of Stars by the Moon, observed at the Tomsk University Observatory during the Year 1928.—Prof S. Chapman and V C A Ferraro The Electrical State of Solar Streams.—Y Ohman Astronomical Consequences of the Polarisation of Fluorescence —W H McCrea The Hydrogen Chromosphere —C L. Janssen Provisional Elements of the Binary System β G C 12307

IMPERIAL COLLEGE CHEMICAL SOCIETY (in Main Chemistry Lecture Theatre, Royal College of Science), at 5 —Dr N V Sidgwick Chemical Linkage

ROYAL SOCIETY OF MEDICINE (Ophthalmology Section) (Clinical Meeting at University College Hospital), at 5

PHYSICAL SOCIETY (at Imperial College of Science), at 5 —Dr E Griffiths and J H Awbery The Dependence of the Mobility of Ions in Air on the Relative Humidity —Prof A M Tyndall Some Unsolved Problems relating to the Mobility of Gaseous Ions—followed by a General Discussion on the Mobility of Ions

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Sir Arthur Keith Demonstration on the Anatomy and Pathology of 'Diverticulitis

ROYAL SOCIETY OF MEDICINE (Clinical Section), at 5 30

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (Annual Meeting) (at Liverpool University), at 6.—L. O Newton Boiler Feed Water

MALACOLOGICAL SOCIETY OF LONDON (in Zoological Department, University College), at 6

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7 —J A Hall Bromide Papers.

MANCHESTER ASSOCIATION OF ENGINEERS (at Engineers Club Manchester), at 7 15 —F B Holt Improvements in Driving Textile Mills

BLACKBURN TEXTILE SOCIETY (at Blackburn Technical College), at 7 30.—J H Place Dobbies.

JUNIOR INSTITUTION OF ENGINEERS, at 7 30.—S. H Hole Road Transport (Chairman s Address)

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (jointly with Leicester Association of Engineers) (at Secular Hall, Leicester), at 7 30.—Dr J Newton Friend Science in Antiquity

INSTITUTE OF METALS (Sheffield Local Section) (at Sheffield University) at 7 30 —W S. Gifford Progress in Electric Furnaces

OIL AND COLOUR CHEMISTS ASSOCIATION (Manchester Section) (at Milton Hall Manchester), at 7 30 —S. T Kinsman The Fastness to Light of Lake Colours.

TEXTILE INSTITUTE (Lancashire Section) (at Manchester), at 7 30 —L. G Lawrie The Microscopical Investigation of Textile Fibres and Fabrics

INSTITUTE OF TRANSPORT (Newcastle-upon Tyne and District Section) (at Y M C A Hall, Newcastle-upon Tyne), at 7 30.—E McClelland Some Aspects of Selling Rail Travel

KEIGHLEY ASSOCIATION OF ENGINEERS (at Keighley), at 8 —A. G Springfield Centrifugal Castings

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Prof T F Tout The Place of Women in Later Medieval Civilisation

SATURDAY, MARCH 9

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (Yorkshire District) (at Town Hall Sheffield), at 3 —W J Hadfield The Local Government Act and the Municipal Engineer

BRITISH PSYCHOLOGICAL SOCIETY (General Meeting) (at Royal Anthropological Institute) at 3 —Prof T H Pear and Miss Edna M Henshaw Some Subtler Skills Conditions for Improvement in Manual Dexterity

ROYAL INSTITUTION OF GREAT BRITAIN at 3 —Sir Ernest Rutherford Molecular Motions in Rarefied Gases (II).

MONDAY, MARCH 11

CAMBRIDGE PHILOSOPHICAL SOCIETY (in Cavendish Laboratory), at 4 30 —N F Mott Quantum Theory of Electronic Scattering in Helium —H M Cave Note on the Number of High Velocity β rays —J L. Hamshere The Mobility Distribution and Rate of Formation of Negative Ions in Air —W Georgeson Thermionic Emission through Double Layers —*Papers to be communicated by title only* —Dr C F Sharman Secondary Electron Emission from Solid Metal Surfaces —J G Semple On Certain Loci of Three Dimensions Representable on Ordinary Space by Means of Cubic Surfaces, and the Cremona Transformations for Ordinary Space obtained by Projection of such Loci.—G de B Robinson A Geometrical Study of the Alternating and Symmetric Groups —G Redington The Effect of the Duration of Light upon the Growth and Development of the Plant —Prof F E Fritsch Evolutionary Sequence and Affinities among Protophyta —M Robertson Life Cycles in the Protozoa.

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge), at 5 —Rear Admiral H P Douglas Echo Sounding

ROYAL SOCIETY OF MEDICINE (War Section), at 5 —Surg -Comdr H Hill Post-encephalitis and its Problems in the Service

ROYAL COLLEGE OF SURGEONS OF ENGLAND at 5 — C E Shattock Demonstration on Specimens illustrating Diseases of the Kidneys

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 6 —Norman Angell Teaching Economics by Visual Demonstration

TEXTILE INSTITUTE (London Section) (at Clothworkers Hall) at 6 —Dr W Gibson Research Work as an Aid in the Sale of Linen Products

INSTITUTION OF AUTOMOBILE ENGINEERS (Birmingham Centre) (at Queen s Hotel Birmingham) at 7 —K Thomas Some Investigations into the Performance of Tubular Radiators for Motor Vehicles

INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Centre) (at Armstrong College Newcastle upon Tyne), at 7 —Ll. B Atkinson How Electricity does Things (Faraday Lecture).

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (Associate Members and Graduates Branch) (at Borough Polytechnic), at 7 —J H Bryant Sprinklers

SOCIETY OF CHEMICAL INDUSTRY (Yorkshire Section) (at Hotel Metropole Leeds), at 7 15 —Prof C H Desch The Nature of Hardness.—H O Neill The Hardness of Metals

CERAMIC SOCIETY (at Stoke-on Trent), at 7 30 —F H Rogers Factory Floors.

INSTITUTE OF METALS (Scottish Local Section) (at 39 Elmbank Crescent, Glasgow) at 7 30 —Open Discussion

MEDICAL SOCIETY OF LONDON (at 11 Chandos Street W), at 8 30 —Dr R. Miller and Dr W G Wyllie Chronic Dyspepsias of Children over the Age of Infancy

INSTITUTION OF ELECTRICAL ENGINEERS (Western Centre) (at Cardiff)

TUESDAY, MARCH 12

ROYAL SOCIETY OF MEDICINE (Psychiatry Section) (Clinical Meeting at Maudsley Hospital) at 4 30

ROYAL SOCIETY OF MEDICINE (Therapeutics Section) at 5.—Dr G Linder and Dr C F Harris Treatment of Chronic Tetany with Steatorrhœa in Adults.

ROYAL COLLEGE OF PHYSICIANS OF LONDON at 5 —Prof E B Verney Polyuria (II).

ROYAL INSTITUTION OF GREAT BRITAIN at 5.15 —Dr S. W Kemp Antarctic Whaling Expeditions (I)

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5 30

INSTITUTE OF MARINE ENGINEERS, at 6.30 —Dr E V Telfer Merchant Ship Service Performance Analysis.

INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (at North British Station Hotel Edinburgh) at 7 —J Wright and C W Marshall The Construction of the Grid Transmission System in Great Britain

INSTITUTION OF AUTOMOBILE ENGINEERS (London Graduates) (at Watergate House, Adelphi), at 7 25 —D Swallow Metal Omnibus and Car Bodywork

INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND (at 39 Elmbank Crescent, Glasgow), at 7 30 —Eng Capt. J C Braud Pulverised Fuel To-day

QUEKETT MICROSCOPICAL CLUB, at 7 30 —Dr Philippa Esdaile Some Household Pests

PHARMACEUTICAL SOCIETY, at 8 —Sir Herbert Jackson The Nature of the Changes which take place in Various Forms of Glass (Lecture)
ROYAL ANTHROPOLOGICAL INSTITUTE, at 8 30 —L Abbé Breuil Essai de co ordination des faits géologiques relatifs aux industries paléolithiques anciens au sud et sud est d Angleterre.

WEDNESDAY MARCH 13

INSTITUTE OF METALS (Annual General Meeting) (at Institution of Mechanical Engineers), at 10 A M —Prof P Saldau Special Properties of Eutectics and Eutectoid Alloys in Binary Metallic Systems.—F Hargreaves and R J Hills Work softening and a Theory of Intercrystalline Cohesion —G B Brook and G H Stott The Testing of Electro-deposits on Aluminium —At 2.—Dr P J Durrant The Constitution of the Cadmium Rich Alloys of the System Cadmium Gold —D Marie I V Gayler and G D Preston The Age hardening of some Aluminium Alloys —C Blazey Brittleness in Arsenical Copper (II).—Dr P J Durrant The Haughton Hanson Thermostat A Method of Flue Adjustment —Dr W Hume Rothery and E Rounsefell The System Magnesium-Zinc
NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (Newcastle upon Tyne) at 7 15 —M Waters The Problem of High Voltage Measurement
HALIFAX TEXTILE SOCIETY (at Halifax) at 7 30 —J H Edmundson Treatment for Trade Effluent from Textile Trades
ROYAL SOCIETY OF ARTS, at 8 —R. P G Denman Loud Speakers
SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) (jointly with Royal Philosophical Society of Glasgow) at 8 —Dr J A Cranston Bicentenary Address on Joseph Black
EUGENICS SOCIETY (at Linnean Society), at 8 —Dr Margaret Rorke and Mr Weatherall Heredity in Education
ELECTROPLATERS AND DEPOSITORS TECHNICAL SOCIETY (at Northampton Polytechnic Institute) at 8 15 —J W Perring Electroplating Plant
INSTITUTE OF FUEL —F W Goodenough The Industrial Use of Gas
HASLINGDEN DISTRICT TEXTILE SOCIETY (at Grammar School Haslingden). —C A Harrington The Weaving of Artificial Silks

THURSDAY, MARCH 14

INSTITUTE OF METALS (Annual General Meeting continued)(at Institution of Mechanical Engineers) at 10 A M —H C Lancaster The Importance of Design and Setting of Large Kettles used for Refining and Low Melting Point Alloys - Dr W Rosenhain and W E Prytherch An Improved Form of Electric Resistance Furnace —Dr F Campbell Recent Developments in Electric Furnaces —At 2 —C Sykes Alloys of Zirconium (II).—Dr J Newton Friend and W E Thorneycroft The Resistance of Zinc to Indentation (A Preliminary Account) —Dr J Newton Friend The Solution of Plain and Amalgamated Zincs in Electric Batteries —Dr J Newton Friend and W E Thorneycroft The Silver Contents of Specimens of Ancient and Medieval Lead
ROYAL SOCIETY at 4 30 —Discussion on Ultramicroscopic Viruses infecting Animals and Plants (continued)
IMPERIAL COLLEGE CHEMICAL SOCIETY (in Main Chemistry Lecture Theatre Royal College of Science) at 5 —Prof C K Ingold The Significance of Tautomerism
LINNEAN SOCIETY OF LONDON at 5 —Dr E J Allen The Origin of Adaptations (Hooker Lecture)
LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society) at 5 — N S Koshliakov Note on the Remainders in the Asymptotic Expansions of Bessel Functions —J E Littlewood The Quadratic Equation in Quaternions.—C E Walsh The Multiplication of Certain Series
ROYAL COLLEGE OF PHYSICIANS OF LONDON at 5 —Prof E B Verney Polyurin (III)
ROYAL INSTITUTION OF GREAT BRITAIN at 5 15 —Rev W H Draper The Handling and Interpretation of Metaphor
INSTITUTE OF CHEMISTRY (Liverpool and North Western Section) (at Liverpool University) at 6 —R. B Pilcher Alchemists in Art and Literature
INSTITUTION OF ELECTRICAL ENGINEERS at 6 —T N Riley and T R Scott Electrical Insulating Papers for the Manufacture of Power Cables — S G Brown and P A Sporing The Prevention of Ionisation in Impregnated Paper Dielectrics
ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6 30 —Wing Comdr G B Hynes Engine Performance Tests
SOCIETY OF CHEMICAL INDUSTRY (Birmingham and Midland Section) (Annual Meeting) (at Engineers Club Birmingham), at 7 —The Chairman and others Miscellany
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Colour Group) (Annual General Meeting), at 7
WEST CUMBERLAND SOCIETY OF CHEMISTS (at Workington) at 7 —Dr Briggs The Preparation of Coal for Sale
OPTICAL SOCIETY (at Imperial College of Science) (Annual General Meetings) at 7 —At 8 —Ordinary Meeting.—W D Wright A Re determination of the Trichromatic Coefficients of the Spectral Colours —Dr J S Anderson On the Testing of a Novel Photographic Shutter
INSTITUTION OF ELECTRICAL ENGINEERS (Dundee Sub-Centre) (at University College Dundee) at 7 30 —W Woodliwiss Distribution
ROYAL SOCIETY OF MEDICINE (Neurology Section) at 8 30 —Cinematograph Demonstration of a Film showing Work on Conditioned Reflexes in Prof Pavlov s Laboratory Leningrad
BRITISH INSTITUTE OF RADIOLOGY, at 8 30

FRIDAY MARCH 15.

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botanical Lecture Theatre Imperial College of Science and Technology) at 2 30 —Sir John Russell Some Agricultural Problems in Australia.—F L McDougall The Commonwealth Council of Science and Industry in its Relation to Agriculture.
ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 4.30 — Thunderstorms and the Maintenance of the Earth s Electric Field Chairman, Prof S. Chapman Discussion to be opened by Prof E V Appleton and continued by R. A. Watson Watt, Dr G C Simpson Prof C T R Wilson and T W Wormell
BIOCHEMICAL SOCIETY (Annual General Meeting) (in Department of Physiology and Biochemistry, University College), at 4 30 —I S. MacLean Further Observations on the Sterols of Yeast.—H J Channon and A C Chibnall The Isolation of n nonacosane and di n tetradecyl Ketone from Cabbage Fat —J G Davis and A T R. Mattick The Metabolism of a Pigmenting Anaerobic Bacterium.—G N Richardson and R K. Cannan Reaction of Azine Compounds with Proteolytic Enzymes —B C Guha and Prof J C Drummond Observations on the Concentration of Vitamin B_1 —Prof J C Drummond R. A Morton and K H Coward A Critical Examination of the Methods for the Assay of Vitamin A.—C R Harington and S S Randall Isolation of 3 5 diiodotyrosine from the Thyroid Gland
MEDICAL OFFICERS OF SCHOOLS ASSOCIATION (Annual General Meeting) (at Society of Medical Officers of Health, 1 Upper Montague Street) at 5 — Sir Henry Gauvain The Combined Education of Children Suffering from Physical Defects
BRITISH INSTITUTE OF RADIOLOGY (Medical Meeting) at 5 — Urinary Discussion
ROYAL COLLEGE OF SURGEONS OF ENGLAND at 5 —Sir Arthur Keith Demonstration of Recent Advances in our Knowledge of the Anatomy and Physiology of the Gall Bladder
BRITISH PSYCHOLOGICAL SOCIETY (Esthetics Section) (at Bedford College) at 5 30 —Mrs Roberts (Susan Miles) and others Discussion on Inspiration
SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (Annual Meeting) (at Liverpool University), at 6 —L O Newton Boiler Feed Water
NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Newcastle upon Tyne), at 6.—J H Gibson Mechanical and Transmission Losses in Marine Engines Shafting and Propellers
INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section), at 6 15 —C F J Morgan Wave form Analysis.
SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Cardiff Technical College), at 7 —Annual General Meeting
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group) at 7
SOCIETY OF DYERS AND COLOURISTS (Glasgow Section) (at 7 Gordon Street Glasgow), at 7 15 —F Asquith The Necessity of Application of Fast Colours on Textile Fabrics
JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7 30 —T Grime Locomotive Rating
ROYAL INSTITUTION OF GREAT BRITAIN at 9 —Prof V M Goldschmidt The Distribution of the Chemical Elements
SOCIETY OF DYERS AND COLOURISTS (Manchester Section) —Short Papers

SATURDAY MARCH 16

ROYAL INSTITUTION OF GREAT BRITAIN at 3 —Sir Ernest Rutherford Molecular Motions in Rarefied Gases (III)
GEOLOGISTS ASSOCIATION (North East Lancashire Group) (at Blackburn Technical College) at 7 —J Ranson The Evolution of the Craven Highland
PHYSIOLOGICAL SOCIETY (Annual General Meeting) (at University College).

PUBLIC LECTURES

FRIDAY MARCH 8

KING S COLLEGE at 5 30 —C J Gadd Assyrian Studies in the Present and Future
SURVEYORS INSTITUTION at 5 30 —Prof J S Huxley Heredity and Society (delivered in connexion with the Institution of Professional Civil Servants).

SATURDAY MARCH 9

HORNIMAN MUSEUM (Forest Hill), at 3 30 —R W Sloley The Cave Artists of the Stone Age

MONDAY MARCH 11

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE at 5 30 —Prof F Fulleborn Some Biological and Epidemiological Aspects of Helminthic Infection (Succeeding Lectures on Mar 12 and 18.)
EAST ANGLIAN INSTITUTE OF AGRICULTURE (Chelmsford) at 7 — F R. Petherbridge The Spraying of Fruit Trees.
ROYAL SOCIETY OF ARTS, at 8. —G Mowlem Burt The Making of a Modern Building with Cinema Illustrations (Bessom Gift Chadwick Lecture)

THURSDAY, MARCH 14

FARADAY SOCIETY (at Chemical Society), at 2 30 —Prof V M Goldschmidt Crystal Structure and Chemical Constitution and General Discussion on same subject by Dr W T Astbury, Dr J D Bernal Sir W H Bragg Prof W L Bragg Prof P P Ewald, Prof F M Jaeger, Dr N H Kolkmeijer Mrs K Lonsdale Prof T M Lowry Dr H Mark Dr A Muller Dr H S Piper F I G Rawlins Prof A Reis, Prof E Schiebold Dr K Weissenberg and Prof A Westgren

SATURDAY, MARCH 16

No 3098, Vol 123]

The Natural History Museum at South Kensington

ZOOLOGISTS, by an overwhelming majority in open meeting, have expressed their sense of dissatisfaction at the present system of control of the British Museum of Natural History, which is mainly devoted to their science, and is regarded by them as their place of reference for all questions relating to the different species of animals This Museum is a branch of the British Museum, the home of which is at Bloomsbury, its chief func tion being the care of art and ethnological collec tions and the maintenance of a Library It is governed by a Board of fifty one Trustees, of whom the Archbishop of Canterbury, the Lord Chancellor, and the Speaker of the House of Commons are Principal Trustees [1] There is also a trustee appointed by the Sovereign, and twenty four official trustees Among these are the president of the Royal Society and the president of the Royal College of Physicians—the sole representatives of the natural sciences There are in addition nine representatives of families whose magnificent gifts have enriched the State Several distinguished men of science are included, however, among fifteen trustees 'elected' by their colleagues on the nomination of the principal trustees

The trustees act through a standing committee of twenty members, which meets ten times a year at Bloomsbury and eight times at South Kensing ton This committee consists largely of the elected trustees "appointed because they are known to be interested in the work as well as competent," and it guides the administrative business of each museum in an efficient manner The direction, however, of a museum of natural history is very different from that of a picture gallery or an art museum the problems which come before the governing body for solution require, therefore, a different kind of knowledge, and unless governed on different lines, neither institution can achieve full success or have full scope for development Indeed, it is obvious that the policy of the Natural History Museum is controlled by its director, and his duty—to maintain its collections—necessitates the choice of a systematic specialist, a side in creasingly separating year by year from university and industrial research To assist the director effectively, he requires a representative body of naturalists and industrialists as trustees , and such

[1] A full account of the method of governing the Museum is given in the very interesting Memorandum presented by Sir Frederic Kenyon to the Royal Commission on National Museums and Galleries and printed in the volume of evidence, p. 51

a body would not have the requisite knowledge or interest for the care of the priceless collections at Bloomsbury

Under these conditions it is necessary to consider the advisability of severing the bonds which bind the two sides of the British Museum together The director of the British Museum is the head accounting officer for both, and hence alone has access to the Treasury While preserving their connexion and governance, a separate accounting branch for the Natural History Museum was offered, but its then director refused, not wishing to be troubled while he had a building free from congestion, and a science at that time scarcely connected, even remotely, with public health and industry This change might be made now, but, while certainly beneficial, does not go to the root of the matter Rightly or wrongly, naturalists have shown their dissatisfaction with the present arrangements by repeated memorials to the Government of the day during the last sixty years In 1866, while the collections were still housed at Bloomsbury, they presented a memorial to the Chancellor of the Exchequer in which they state their view in clear terms "We are of opinion that it is of fundamental importance to the progress of the Natural Sciences in this country that the administration of the National Natural History Collections should be separated from that of the Library and Art Collections, and placed under one officer who should be immediately responsible to one of the Queen's Ministers" To this memorial twenty five signatures only were appended, but they were those of the foremost naturalists in the country, Charles Darwin, Huxley, Hooker, Lord Lilford, Wallace, and others—men of international renown

The Royal Commission on Scientific Instruction and the Advancement of Science took evidence on this matter with great care The commissioners summarise the evidence they received by expressing their opinion in 1874, "that the objections to the present System of Government of the British Museum by a Board of Trustees, as at present constituted, so far as relates to the Natural History Collections, are well founded, and we have been unable to discover that the system is attended by any compensating advantages" They recommended that the director "should be appointed by the Crown and under the control of a Minister of State, to whom he should be immediately responsible" They also suggested an expert Board of Visitors, the members of which should be appointed for a limited period, but be re eligible, and who should make annual reports to the Minister, to be laid before Parliament

Nothing was done, and the Council of the British Association in 1879, a bill having been passed in the previous session to authorise the trustees to transfer the Natural History Collections into the new building at South Kensington, without any reference to a separation in governance, memorialised the First Lord of the Treasury to this end, but without effect The superintendent of the Natural History Museum was made director in 1885 with a comparative independence, which was revoked in 1898 In 1908 a deputation, representative of zoology, botany, and geology, was received by the Prime Minister (Mr Asquith) and asked for a full official inquiry into the organisation of the Natural History Museum This was refused, as the trustees are a statutory body with whom the Government is powerless to interfere, an extraordinary position for a Prime Minister He sympathised with the view that the director should have a free hand in the management of his department, and promised to convey to his fellow trustees of the British Museum all that the deputation had suggested No alteration, however, was made

In the meantime zoology has advanced by leaps and bounds It is no longer a subject of purely philosophical interest That the facts of heredity in man and animals are vital to the due governance of any State is now clear Fisheries to a large extent depend on the study of the development of fish and of their habits at different ages in relation to the physical and chemical conditions of the water in which they live The study of wools, silks, and hides has materially affected important industries, and all breeding is carried on for specific ends, for food, for transport, or for raw products of manufacture The microscopical study of unicellular animals has resulted in the amelioration of the lot of mankind in respect to malaria and many other diseases, and scientific measures are in force over a large part of Africa against sleeping sickness The Imperial Bureau of Entomology has its centre in the Natural History Museum, much of its work based on the national collections, and especially cares for crops so far as insect and other attacks are concerned Many molluscs are valuable as food, some for their shells, and the study of corals and marine plants is necessary in respect to navigation in the tropics Indeed, there is to day the recognition that the study of animals is vital to man's civilisation and progress, and all our colonies employ specialists to apply the laws of their science

These laws are largely the aims in research at the universities, the understanding of the structure in relation to the manifold activities of the living matter upon which all organisms depend The two sides of this and of all sciences are inextricably bound, for progress in understanding must always precede scientific application

Representatives of all these aspects of animal life look to the Natural History Museum to catalogue and to store specimens for reference, and there is not a single group which is free from their activities All animals have fundamental points of relationship, and it is commonly essential for an investigator to have to refer to a dozen or more forms in as many groups They are vitally interested in the Natural History Museum, and they cannot agree, to day, with Mr Asquith in 1908, that the trustees are "equally cognisant of natural history and archæology" in the sense of knowledge of the needs of scientific and applied zoology They do not see how due representation of their present and future aims can be given without such a large increase in the body of trustees as to amount to a complete reconstruction They consider that the Museum in future will have to extend its activities into the field and to collect the animals it requires, if it is to maintain its utility A director brought up within its walls for twenty or thirty years will even, in the next decade, be necessarily out of touch with his fellow zoologists outside, yet it would be deplored if his post, which should be the ambition of every member of the staff, should on a vacancy be filled necessarily from outside

With these views scientific men generally find themselves in cordial agreement They ask for no exceptional treatment, only for their affairs to be managed by a board of governors, which may be divided into those who have knowledge and judgment in respect to their activities, and those who are interested in the successful prosecution of such for national ends We feel that there is no reason to perpetuate any form of governance by trustees or otherwise, if a better method can be devised Evolution is equally a law in organic science and in national affairs, and for the welfare of both, progress is essential No State is wise to refuse inquiry if any class of its subjects clearly demands it, and there seems to be practical unanimity here Fortunately, a suitable body for such investigation is in existence—the Royal Commission on National Museums and Galleries, and the evidence submitted is so cogent and suggestive that we are confident it will lead to constructive conclusions

British Floods and Droughts

British Floods and Droughts By Dr C E P Brooks and Dr J Glasspoole With an Introductory Note by Dr Hugh Robert Mill Pp 100 +2 plates (London Ernest Benn, Ltd, 1928) 10*s* 6*d* net

THIS book will attract many readers by its title, and they are not likely to be disappointed in its contents, which embrace entertaining accounts of notable floods and droughts in the British Isles back to quite early times, together with a wealth of statistical data about rainfall fluctuations compressed into a comparatively small volume In the rain rich climate of the British Islands, flooding is perhaps a more familiar condition than one of drought, but, as the authors truly observe, the vicissitudes neither of one nor the other are anything but mild compared with what occur in many other countries In fact, it would be true to say that the climate of these islands is well balanced or even tempered, not in spite of its variability but because of it, inasmuch as excesses in any direction rarely last long enough to pass from the stage of an entertaining diversion from the monotony of normal conditions into that of serious distress and danger In other words, the weather here provides plenty of stimulus, physical and mental, at a smaller cost in life and suffering than is the case in some parts of the world

After an introduction on the general subject of rainfall in the British Isles, Dr Brooks and Dr Glasspoole, experts in this subject, arrange the fourteen chapters of their book into three parts I Great Rains and Floods, II Droughts, III Variations of Rainfall British floods are of several types The most familiar floods are the widespread, slowly rising river valley floods that may follow excessive rainfall at any season of the year, but most frequently in winter when melting snow may also be a factor The great Thames floods of November 1894, the Severn floods of May 1886, the Tees floods of September 1927, the Norwich floods of August 1912, the destructive thaw floods in the Scottish Highlands of January 1892, the historic Morayshire inundations of August 1829, are all outstanding examples of this class of flood The Norwich flood forms the subject of the frontispiece It was caused by a cyclonic downpour yielding 8 inches of rain in 24 hours on the top of previous heavy rains

Floods of the 'cloud burst' type in association with summer thunderstorms are more localised but also more dangerous, for they rise suddenly

when 5 or more inches of rain come down in a few hours of storm, and the water seems to fall in a solid sheet The Louth disaster of Whitsuntide 1920, when 22 persons were drowned, as a great thunderstorm burst over the Lincolnshire Wolds, was of this character A similarly impressive storm took place at Driffield at the foot of the Yorkshire Wolds on July 3, 1892 Cloudbursts, however, have been peculiarly prolific in the mountainous districts of South Wales and along the bold Pennine-Cheviot backbone of northern England On July 2, 1893, one such storm bursting over the wilds of the Cheviots ploughed up many acres of black peat on the desolate fellside of Bloodybush Edge, Northumberland

Of tidal floods, the most serious of modern times was that of Jan 6, 1928, on the east coast and up the Thames estuary, taking toll of fourteen lives in London It was due to the combined factors of a spring tide, a severe gale in the North Sea, and an upper Thames charged with snow water In the Middle Ages when, according to Prof Otto Pettersson, both the tide raising forces and the storminess were at a maximum, tidal floods caused enormous devastation and loss of life on the North Sea coast both of England and Holland We have also floods due to the failure of dams, as when 245 lives were lost by the bursting of the Bradfield Reservoir, near Sheffield, on Mar 11, 1866

British droughts appear to have been severe in the eighteenth century, but in modern times the worst droughts of a protracted character were probably those of 1887 in the north west of England and 1921 in the south east, when there was a great dearth of water and milk in many districts The great spring drought of 1893, however, was more acute while it lasted, many places in Kent and Sussex, as well as London, experiencing two or more absolutely rainless months Dry weather, while it lasts, can be very intense in the wet western parts of the British Isles, but it has more definite bounding dates without the periods of faltering rainfall before and after, which are sometimes so pernicious in the dry eastern parts

The book contains useful information about the extreme variations of rainfall since the establishment of reliable rainfall records on an extensive scale, that is, from about 1870 Thus the highest annual rainfall total on record is 247 inches at the Stye Head, Cumberland, in 1923, and the lowest, 10 inches, at Margate, in 1921 , but the latter year was only the driest in the south east of England, whilst the former was nowhere near the wettest over the British Isles generally The highest two daily totals, close to 9½ inches, both, curiously enough, belong to Somerset, the one case at Bruton on June 28, 1917, and the other near Bridgwater on Aug 18, 1924 The longest duration of *absolutely* continuous rainfall, namely, 58½ hours, is on record for Camden Square, London, between 1 P M on June 11 and 11 30 P M on June 13, 1903 As the duration of continuous rain is an interesting and important aspect of climate, it is to be regretted that the authors do not warn their readers that the number of self recording rain gauges is relatively small, and that it is unlikely that London really holds such a record In the hill districts of Britain where the rainfall is excessive, bad weather is often of a most unrelenting character Rain that will cease for an interval in the plains has there a way of simply altering its character, of changing its tune, so to speak, from heavy driving sheets to a teasing, drenching drizzle, and back again, and it is highly probable that in the high hills sixty or more hours of continuous rain is not very uncommon

The methods adopted by the authors for estimating the rainfall of the country to a good approximation in earlier periods when rain gauges were few are ingenious, whilst their treatment in the last chapter of the study of weather periodicities and recurrences is cautious but suggestive The periodic component in the make up of the weather is, as Capt Brunt has shown, small, and of very little use in forecasting , but the curves produced by Drs Brooks and Glasspoole permit of a hope, though not a forecast, that the tide is about to turn, and that the wet spell of years that has marked the first quarter of the century, and especially the last six years, will soon be broken, with a tendency to finer summers May we say, however, that we think the authors have been a little too insistent in their emphasis on the dismal side of rainy summers like 1924 and 1927 ? Excessive summer rains are admittedly inconvenient and may worry the farmer, but they bestow lavish beauty upon earth and sky and play no small part in the making of " England's green and pleasant land " The form and lighting of the clouds and the wild and fantastic sunsets in a rainy summer are incomparable ! Moreover, there are always plenty of delightful intervals and ideal days in the worst of summers if people would only choose to see them, and in this connexion the authors rightly point out that the wet August Bank Holiday of 1927 gave the whole summer a reputation which it did not deserve

Scottish Ornithology

The Geographical Distribution and Status of Birds in Scotland By Evelyn V Baxter and Leonore Jeffery Rintoul Pp vii + 425 (Edinburgh and London Oliver and Boyd, 1928) 15s net

THE feathered population of the British Isles has been subjected of late years to scrutiny so intense as to cause misgiving, and in some cases indignation, among such lovers of birds as are not specialists

The conditions necessary for the satisfaction of the scrupulous framers of ornithological statistics imply the slaughter, euphemistically termed the 'collection' or 'securing,' of very many harmless birds In the *Zoologist* for January 1913, Dr C J Patten, in discussing the reported occurrence of four Redbreasts, *Erithacus rubecula*, at the Tuskar Lighthouse, remarked "The birds were not captured, and so these occurrences cannot carry the same weight that they would had the specimens been secured and forwarded for corroboration "

In their volume on "The Geographical Distribution and Status of Birds in Scotland," Miss Baxter and Miss Rintoul are at pains to distinguish between the British and Continental forms of several species In regard to the Redbreast, for example, while they record the British form as resident in every part of Scotland except Shetland and St Kilda, the Continental variety is reported from only fourteen localities Now, whereas the difference between the two subspecies cannot be detected until specimens are in hand, hundreds of Redbreasts must have been 'collected' to establish a fact not of first-rate importance We do not accuse the authors of a direct share in such slaughter, but their statistics are founded on the result of industry in that line on the part of others, and they inform the reader in the preface that "a great deal of work remains to be done before we have a comprehensive knowledge of the status in Scotland of even our commonest birds "

We note with satisfaction that the authors observe timely reticence by withholding information about certain scarce birds, remarking that "in some instances in the interests of birds themselves it has been necessary to suppress the localities where they breed, for example, the Greenshank in Southern Scotland " It would have been well to observe the same precaution in respect to some other species—the Chough, for example, which formerly used to breed in many parts of Scotland but is now resident in two places only, where it is in imminent danger of extermination owing to the hostility of jackdaws and the baneful industry of collectors

The authors consider it expedient to comply with modern practice in duplicating specific names, and I suppose we must not attribute it to a deficient sense of humour which sanctions the diminutive wren to be heralded as *Troglodytes troglodytes troglodytes*, but surely injustice is done to the great pioneer of classification by adding (L) to these cumbrous titles Linnæus was content to denote the wren as *Motacilla troglodytes*, and assuredly he would have disclaimed having laden the Grey Plover with such cacophonous polysyllables as *Squatarola squatarola squatarola*! Clumsy nomenclature such as this causes the enemy to blaspheme and friends to complain In such cases as it may be desired to duplicate the specific name, this might be conveniently indicated by adding a numeral (2)

The Buffet headed Duck, *Clangula albeola*, is not mentioned in the volume under review, although Yarrell records a solitary instance of its occurrence in Orkney in 1841, and states that the bird was to be preserved in the Natural History Museum at Margate

The foregoing frank criticism must not be interpreted as unfavourable to what is a thorough piece of work, which must have cost the authors no slight labour to compile and will prove very useful for reference HERBERT MAXWELL

Crystal Physics

(1) *Lehrbuch der Kristallphysik (mit Ausschluss der Kristalloptik)* Von Prof Dr Woldemar Voigt Nachdruck der ersten Auflage ergänzt durch eine spätere Arbeit des Verfassers und mit einem Geleitwort von Prof M v Laue (Sammlung von Lehrbüchern auf dem Gebiete der mathematischen Wissenschaften mit Einschluss ihrer Anwendungen, Band 34) Pp xxvi + 978 (Leipzig und Berlin B G Teubner, 1928) 41 gold marks

(2) *The Physics of Crystals* By Dr Abram F Joffé Edited by Prof Leonard B Loeb Pp xi + 198 (New York McGraw Hill Book Co, Inc, London McGraw-Hill Publishing Co, Ltd, 1928) 15s net

(3) *Bibliography of Crystal Structure* By Jared Kirtland Morse Pp xix × 164 (Chicago University of Chicago Press, London Cambridge University Press, 1928) 15s net

IT cannot be too strongly emphasised that crystal physics is no longer a highly specialised branch of physics, dealing with solid matter in what was

formerly thought to be a comparatively rare state The new crystallography has shown, by the study of the interaction of X rays and solids, that the normal stable state of most, and probably all, solid matter is essentially crystalline, that is, there is always a tendency for a group of ions, atoms, or molecules of the same kind to arrange themselves in the solid state in an orderly way Even such substances as stretched rubber and gelatin, and the fibres of our bodies, have given evidence of an orderliness in the arrangement of the units from which they are built This new outlook makes specially welcome the present volumes on crystal physics

(1) Since Voigt's "Lehrbuch der Krystallphysik" has been reprinted by the photomechanical process, it is identical, save for a few additions, with the original edition of 1910 Its outlook is therefore essentially that of classical crystallography The whole field is covered from geometrical and mechanical to electrical properties of crystals There is, unfortunately, no index Naturally, for particular subjects one would look to other sources, such as Love's "Elasticity" or the Geiger and Scheel "Handbuch der Physik," but there is no other book covering the work up to 1910 so well The treatment is mathematical wherever possible, and there is for the research worker too little detail of experimental methods Nevertheless, this reprint is of value, and since the original is so comprehensive and the outlook so classical, it would be much simpler to write an entirely new book than to revise Voigt's monumental work In its present form it gives the research worker a good idea of the many types of research possible in crystal physics

(2) In Joffé's book we have an attractive account of twenty five years' research upon certain problems relating to the elastic and electrical properties An invitation to give a course of lectures in the University of California was used as an opportunity to organise into a consistent whole the results of many researches carried out by Joffé and his collaborators The outlook is fundamentally modern, as can be seen by the opening of the first lecture, where a crystal is defined as a regular arrangement of small units (atoms, ions, or molecules) The electrical theory of crystal lattices is developed, and it is pointed out that no more than the 10^{-15} part of the space is occupied by the electrons and nuclei, the crystal being regarded as an empty space with small charged particles distributed at enormous distances apart

In the first six lectures it is shown how the general predictions of the electrical theory were checked both qualitatively and quantitatively by a diverse series of experimental studies upon the elastic properties of crystals The fascinating account of these experiments admirably conveys the impression of research workers absorbed in their work and ready to adopt any tactics to solve their particular problems For example, no sooner is the X ray Laue method well established than it is applied to the study of the elastic limit (Lecture IV) with results not easily attainable by other methods

The remaining eleven lectures deal with certain electrical properties of crystals in a way that gives the reader the thrill of research well and truly carried out For other research workers there is perhaps too little of that important section of research laboratory, the library In the chapters on the mechanical properties of crystals, one looks in vain for such names as Carpenter, Elam, and Taylor The book must not, therefore, be used as if it were a summary of work so far done in the subjects Its title is misleading, since in the preface it is clearly stated that only a limited portion of the field of the elastic and electrical properties of solids is covered Some of the work discussed would, however, otherwise be available only in Russian The English is sometimes a little difficult, for example, a statement in the preface that "all atoms of a crystal are in the same relative position" is untrue, as it stands The most notable feature of the book is that such interesting and valuable work is presented so as to make the reader feel that he is himself discovering the facts with the research workers in the laboratory

(3) We turn now to the third volume, which is published as the first *Bulletin* of the Crystal Structure Laboratory of the University of Chicago The greater part of this is a bibliography of publications on crystal structure and related topics published between 1912 and 1927 The classification is into sixteen groups according to the year of publication, and the papers of each year are arranged alphabetically under authors The title of each paper is given in English Joint papers are placed under the name of the author whose name appears first on the paper, but there are no cross references A set of reprints of one well known worker was used to test the completeness of the bibliography Four out of eight papers had been omitted, one from the *Phil Mag*, one from the *J Chem Soc*, and two from the *Min Mag*, all well known journals In spite of this the bibliography seems to be very comprehensive, and its use will be very considerably increased when an index is provided in one of the later *Bulletins*

In order to make known ("better known" in the original) the work of the Crystal Structure Laboratory, the bibliography is preceded by an introduction which is largely made up of terminological inexactitudes and is often in questionable taste In one place a programme of investigation of the laboratory is given, consisting of a list of apparently every known type of work in X ray crystallography classified into four sections We are then actually told that "already fundamental contributions have been published in the majority of these sections" We need be in no doubt as to what these fundamental contributions are "The most striking and important contributions of the Crystal Structure Laboratory to date have been in the solution of the structure of these two substances —methane and benzene" The papers giving the solutions are reprinted in the *Bulletin*, and appear to be nothing more or less than interesting speculations They certainly do not justify the statement that 'the structure of the benzene ring has been solved" The crystal structure proposed for ethane is not even hexagonal, and the paper suggests that the author is unaware of this disagreement with crystallographic evidence Moreover, the normal procedure of the X ray crystallographer is to reject a proposed structure if observed and calculated intensities of X ray reflections disagree Mr Morse prefers to suggest that such disagreements between his own proposed structures and the experimental observations of others "may lead to a fundamental revision of our present simple notions concerning the scattering of atoms"

Apparently the only structure work that has been completed in the Laboratory is a determination of the space group of certain sulphates For this purpose the Laue method alone was used Whilst it is true that really able workers, such as Wyckoff, have used this method exclusively with great success, the tendency nowadays is not to rely solely upon one method There appears to be little point in equipping this Laboratory so fully if the full advantages available are neglected

The thought of possible injury to the feelings of Mr Morse and the University of Chicago caused the reviewer to hesitate long before referring thus to the first publication of a newly established Laboratory, but some expression should surely be given of the sense of injury produced in the, comparatively speaking, poverty stricken research workers in pure science in Great Britain when they see part of the world's research funds used in this way while so many problems lack the support needed for their investigation W H GEORGE

Our Bookshelf.

Sheep Production By Levi Jackson Horlacher (McGraw Hill Publications in the Agricultural and Botanical Sciences) Pp x+418 (New York McGraw Hill Book Co, Inc, London McGraw Hill Publishing Co, Ltd, 1927) 20s net

THIS book is partly the result of the impetus which has been given to the sheep industry in the U S A during the last five years, and its consequent repercussion on the enrolments in courses on sheep husbandry in the American agricultural colleges It is written primarily for the sheep producer of America In consequence, its value to the British agriculturist is not excessive To the student of animal ecology, who may desire a rapid survey of the growth and distribution of the sheep industry in the United States, it will be useful The treatment, while not exactly exhaustive, cannot be described as superficial A large amount of information, hitherto only available in *Bulletins* and *Circulars* of the U S Department of Agriculture and in various publications from State experimental stations, has been gathered together under one cover, and made readily available by a satisfactory index

The book is divided into four parts An introductory portion describes the history and development of sheep production, anatomy (briefly), judging, and feeding and digestion General accounts of each are given, which, while adequate for the needs of the agricultural student, are of little use to the advanced worker Part 2 consists of an account of the general principles of sheep breeding, with a description of each of the breeds of American importance Part 3 deals with the establishment and management of a flock, having regard to the suitability of certain breeds and crosses for different localities and markets available Methods of production for mutton and wool are well and clearly stated, and this part will probably be of greatest interest to British readers The concluding part consists of a short glossary of terms connected with sheep and wool

The book is, on the whole, well written, opinions are clearly stated, and logical reasons are offered for most of the conclusions drawn The illustrations, of which there are 137, are either diagrammatic or reproductions from photographs, and are mostly very good, although the American tendency to include landscape views, which either have but little bearing on the subject or mask its outlines, is evident in a number of them The publishers have done their part of the work in their usual satisfactory manner

La chimie d'hier et d'aujourd'hui Par Dr A Kirrmann Pp vii + 148 (Paris Gauthier-Villars et Cie, 1928) 15 francs

THIS is an interesting little book, which may be read with profit by the layman and with pleasure by the enterprising student of chemistry, so far as we are aware, it has no exact counterpart in English It is very successful in affording within a modest

compass a very readable general account of the nature and scope of modern chemistry, of the problems which the chemist has to face, and of his methods of attacking them in the laboratory In tracing the historical development of chemistry, the author rightly insists that "rien ne pouvait ensuite mieux préciser le caractère de cette science que l'étude de son développement historique, de l'évolution des idées directrices et de la description de l'enrichissement progressif des connaissances humaines"

The work contains a short list of technical terms and thumb nail biographies of some fifty celebrated chemists of the eighteenth century and later The *cognoscenti* will appreciate the statements that among the qualifications of the successful research worker are "une imagination active," "une grande habileté manuelle," "une patience sans bornes," and "une érudition suffisante pour éviter de s attaquer à des questions déjà résolues" We commend also to the attention of all optimistic candidates for the Ph D after nine terms' research the closing sentence of this chapter "Le travail de laboratoire peut être terriblement ingrat et le moindre résultat exige une dépense sans compter et de temps et d'efforts" J R

Die Physik, 1914–1926 Siebzehn ausgewählte Kapitel Von Prof O D Chwolson Aus dem Russischen übersetzt von Georg Kluge Pp ix + 696 (Braunschweig Friedr Vieweg und Sohn, A G, 1927) 35 gold marks

This volume is similar in many respects to Prof Andrade's "Structure of the Atom," both in its scope and in the obvious enthusiasm with which it has been written It partakes, however, rather more of the nature of a collection of independent essays, whilst it has a natural bias towards the German and Russian points of view Written as an appendix to Prof Chwolson's general text book of physics, it had its origin in an attempt to summarise for Russian students the work done elsewhere between 1914 and 1922, when the country was isolated, how well it has succeeded may be judged from the fact that it has been translated into French as well as into German

A commendable balance between theory and experiment has been maintained throughout, and there is a satisfactory selection of good figures and of tables of numerical data, whilst each section includes a bibliography Physics has advanced considerably since 1926, but even where much new ground has been broken, Prof Chwolson's accounts of the older researches are stimulating, and should be particularly valuable for physics students starting for the first time on experimental research.

Cambridge Observations Vol 24, Part 2 *Catalogue of Zodiacal Stars for the Equinox 1900 0 from Observations made in the Years 1900–1918* Pp vi + 58 (Cambridge At the University Press, 1928) 5s net

Sir David Gill indicated the importance of accurately surveying all the brighter stars in the zodiacal region, to render them available as comparison stars for the moon and planets Of late years the value of such observations has been further emphasised, since Prof Brown, Dr Spencer Jones, and Dr Innes have all shown that very accurate determinations of the moon's errors can be obtained from observations of the occultations of stars, provided that good positions of the latter are available The Cambridge University Observatory has been engaged since 1900, but with many interruptions, in observing the stars in Sir David Gill's list, and a catalogue containing positions for 1900 0 of 2588 stars out of the 2798 in Gill's list has been published The average number of observations of each star is about five, very few have less than three observations in each co ordinate The observations are not fundamental, but depend on Newcomb's positions of the standard stars Magnitude equation has been applied, it is nearly the same for all the observers, being in the mean 0 01 sec for magnitude 4 5, and increasing fairly uniformly to − 0 08 sec for magnitude 9 0

The Right Ascensions were observed by eye and ear up till 1914, and by chronograph in 1917–1918 Proper motions have not been applied

A C D C

A Text Book of Inorganic Chemistry Edited by Dr J Newton Friend (Griffin's Scientific Text-Books) Vol 6, Part 1 *Nitrogen* By Dr Edmund B R Prideaux and Herbert Lambourne Pp xxviii + 242 (London Charles Griffin and Co, Ltd, 1928) 18s net

A volume on nitrogen provides an exceptional opportunity for a chemist who is alert to the interesting features of his science, since such a volume necessarily includes the foremost technical problem of the day, that of the 'fixation' of nitrogen, as well as some of the most hotly debated questions of molecular structure The latter category covers the problems of variable valency, mixed double bonds and co ordination, and even then leaves the stereochemistry of the element to be dealt with in the light of modern knowledge No higher compliment need be paid to the authors than that they have made adequate use of their opportunities, and have produced a volume which does justice to the fascinating element with which it deals

The Ordinall of Alchimy By Thomas Norton of Bristoll Being a Facsimile Reproduction from Theatrum Chemicum Britannicum, with Annotations by Elias Ashmole With Introduction by Dr E J Holmyard Pp viii + 125 (London Edward Arnold and Co, 1928) 10s 6d net

Dr Holmyard has earned the gratitude of all interested in the history of chemistry by his preparation of this book Norton's poem, although it has no particular value from the point of view of the development of chemistry, gives, if it is authentic, an interesting picture of early alchemy in Great Britain, and since the original is difficult to obtain, this reprint (in facsimile) will appeal to many readers

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Eddington's Hypothesis and the Electronic Charge

PROF SIEGBAHN has directed my attention to the paper in the *Proceedings of the Royal Society* for January 1929, p 358, in which Prof Eddington arrives at the relation between the electronic charge e and the ratio $hc/2\pi$,

$$\frac{hc}{2\pi e^2} = 136$$

On page 174 of NATURE for Feb 2, 1929, some editorial remarks are made concerning this relation, and it is stated that "*all* existing experimental evidence are in favour of a value very near to 137" Inasmuch as I have carried out an investigation in this field, the results of which were mentioned in Eddington's paper, but which were published only in *Upsala Universitets Årsskrift*, 1928 (Diss , May 1928), I may be permitted to make a few remarks upon the subject

The commonly accepted value of e ($4\ 774 \times 10^{-10}$ E S U $\pm 0\ 1$ %) was determined by Millikan in 1916 There are, so far as I know, no redeterminations of e which claim the same degree of accuracy In the investigation carried out by myself the absolute wave length of the aluminum $K\alpha$ line was determined by means of a ruled, plane reflection grating From this and the known crystal value of the same spectral line, I computed a new value of e, namely, $4\ 793 \times 10^{-10}$ E S U $\pm 0\ 3$ % In a recent paper (*Phys Rev*, Dec 1928), A P R Wadlund, using the same general method (Compton, 1925), gives a value of e ($4\ 774 \times 10^{-10}$ E S U $\pm 0\ 15$ %) which is exactly the same as that found by Millikan

In order to determine the reliability of these three values, each being the mean of comparatively few determinations, it is of importance to analyse in each case the distribution of the individually determined values around their mean For each of his twenty five investigated drops Millikan obtained a value of $e^{2/3}$, and from the distribution of these single values he has computed the 'probable error' to be $\pm 0\ 025$ % From the published $e^{2/3}$ values I have calculated each single e value From their distribution the 'probable error' was found by the usual methods to be $\pm 0\ 04$ %, which agrees with that found by Millikan related to $e^{2/3}$, namely, $3/2 \times 0\ 025 = 0\ 038$ In the diagram (Fig 1) I have plotted the number (Z) of values falling in the intervals 0 0 1 %, 0 1 0 2 %, etc , from the mean The upper curve represents the error distribution for Millikan's determinations The lower figure is the error distribution curve obtained in the same manner from my own single values (29) My mean value is 4 793 and is 0 4 % greater than Millikan's At the bottom of the diagram I have plotted Wadlund's mean value with its published error limits and also its probable error as given in his paper In his paper only one single value of the nine obtained is published, and if this is indicative of his series of measurements, his error distribution must be considerably wider than either Millikan's or my own The position of the e value belonging to this single value departs by 1 % from the mean, and the corresponding probable error is given as $\pm 0\ 18$ % (see Fig 1)

It should be pointed out that the error limits apportioned to each of these three e values are not computed in the same manner In Fig 1, I have indicated by means of horizontal arrows the probable error Δ_p calculated in the usual manner from the formula

$$\Delta_p = \tfrac{2}{3}\sqrt{\frac{\Sigma\Delta^2}{n(n-1)}},$$

where Δ is the deviation from the mean and n the number of values obtained The arithmetical mean error, Δ_m, is given by

$$\Delta_m = \frac{\Sigma\,|\,\Delta\,|}{n}$$

Millikan's published error limits, Δ_a, agree with the value calculated from the relation

$$\Delta_a = \sqrt{\Delta_p{}^2 + \Sigma\Delta_s{}^2},$$

where the Δ_s are the systematic errors estimated

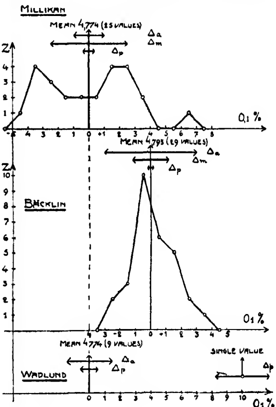

FIG 1

from the method used In my case I have, for the purpose of this calculation, taken

$$\Delta_a = \sqrt{\Delta_m{}^2 + \Sigma\Delta_s{}^2},$$

Δ_m being much greater than Δ_p (see Fig 1) It would require too much space here to explain in detail the error calculations of Wadlund For this I must refer to his paper The diagram is perhaps sufficient

In my opinion it is of more physical significance to carry out such error calculations with the arithmetical mean error Δ_m, than with the so called probable error Δ_p, which is commonly used without the necessary analysis of the error distribution obtained

From the accompanying diagram it is, I believe, clear that from the experimental evidence we can scarcely decide whether 136 or 137 is the better value for Eddington's ratio, especially since h is not known with the same degree of accuracy as e Moreover, it

should be remembered that the value of h is obtained with the aid of a value of e

As to the Rydberg constant R, agreement between the spectroscopic value and that calculated from other physical constants is a criterion not only of the value of e but also of the other physical constants involved (h, e/m)

ERIK BÄCKLIN

Physical Laboratory of the University,
Upsala, Sweden, Feb 15

The Raman and Infra-Red Spectra of Carbon Dioxide

MR RASETTI's examination of the Raman spectrum of carbon dioxide as reported in his letter in NATURE of Feb 9 is of extreme interest He points out (1) a coincidence between (a) the infra red frequencies deduced from the Raman spectrum, namely, 1284 and 1392 cm $^{-1}$, and (b) the wave number difference between the band centres of the double doublet at 2 7 μ and the doublet maxima at 4 25 μ as given by Schaefer and Philipps (*Zeit f Physik*, **36**, 641, 1926), which are 1279 and 1381 cm $^{-1}$, and (2) that there is no known band in the infra red spectrum of carbon dioxide which would correspond with either of these

A further examination of the absorption spectrum mentioned shows that the concordance is far from being a coincidence There is perhaps no physical justification for calculating as Mr Rasetti does, the difference between the maxima in a simple Bjerrum doublet and the band centres in a double doublet Adopting Schaefer and Philipps's nomenclature, we have four double doublets, A, C, F, and K (D and E being uncertain) The assumption of a triangular molecular model with two large and approximately equal moments of inertia, A, and one much smaller, C, gives as a general expression for the double doublet separation,

$$\Delta\nu = \left(\frac{1}{C} - \frac{1}{A}\right)h/2\pi^2$$

(assuming the absence of a zero branch) Now, the average value for this separation in the four bands quoted is 108 cm $^{-1}$, which is 1392 1284 and we should be justified in assuming that the frequencies in question represent such a double doublet

However, the connexion between the deduced values and the observed spectrum is closer still (i) If we determine the wave number differences between the band centres in the double doublets and those in the 'undoubled' bands, we have the values recorded in Table I

TABLE I

Bands	$C \to I$	$K \to B$	$B \to A$
$\Delta\nu$ in cm $^{-1}$	1262 1375	1293 1393	1264 1368

These values are of the same order as the deduced frequencies (ii) If we perform the same operation on the double doublets themselves the agreement is exact, within the experimental error, $F \to A$ giving 1388 and 1282 cm $^{-1}$ (iii) The frequency difference between the undoubled bands is a simple fraction of one of these frequencies, thus $B \to H$ is 687 cm $^{-1}$ (approximately $\frac{1}{2} \times 1392$), and $E \to D$ is 637 cm $^{-1}$ (approximately $\frac{1}{2} \times 1284$) There must consequently be some simple relationship between the double doublet separations and the band centre separations, and we actually find in the two frequencies deduced from the Raman spectrum, that if the former is taken as 107 cm $^{-1}$, we have $1391 = 13 \times 107$, and $1284 = 12 \times 107$

This fact is rendered more prominent by a reconsideration of the emission spectrum as determined by the writer in conjunction with Mr K H Lih (Bailey and Lih, NATURE, **121**, 941, 1928) To account for the regularities in this spectrum, we assumed that the bands could be represented as multiples of a fundamental frequency given by $\nu_0 = 16 \times 10^{11}$, or in wave numbers, 53 5 cm $^{-1}$, *i e* $\frac{1}{2} \times 107$ the half value being adopted to provide for the just perceptible resolution of the band at 2 84 μ Now, if we accept the possible presence of a band at 1284 cm $^{-1}$ (Eucken, *Zeit f Physik*, **37**, 714 (1926), it is interesting to note, postulated the existence of an optically inactive frequency at 7 86 μ, *i e* 1272 cm $^{-1}$) the emission spectrum can be represented in a very simple manner, as will be seen by a consideration of Table II

TABLE II

No	1	2	3	4	5	6	7	8
λ in μ	1 46	1 70	1 99	2 40	2 84	3 12	4 46	(7 80)
ν in cm $^{-1}$ obs	6850	5880	5027	4167	3524	3206	2248	—
ν in cm $^{-1}$ calc	6848	5885	5029	4173	3531	3210	2247	(1284)
n	64	55	47	39	33	30	21	12

The calculated wave numbers are obtained by multiplying $\nu_0 - 107$ cm $^{-1}$ by n, in particular the bands 8, 7, 6, and 4 now become members of a series represented by $3\nu_0(1 + 3m)$ The above results were obtained with a rocksalt prism spectrometer, it is proposed to re examine this spectrum with greater resolution and at higher sensitivity, when possibly other members of the series may be identified It is difficult at the present to see the underlying physical significance of the above results

The Fulcher Bands of Hydrogen

IN a communication just published (in the *Proceedings of the Royal Society of Edinburgh*) I have shown that the Fulcher bands of hydrogen can be arranged in three branches (P', Q, and R'), the Q branches being identical with those of Richardson The P' and R' branches have an initial level differing from that of the Q branch, while all three have a common final level, a fact proved conclusively by the intercombinations found to hold between them This shows the final state to be an S state, as Birge has predicted

It is of interest to inquire how these hydrogen bands fit in with the new mechanics, and in particular to determine the constant σ in the term form

$$B\{j(j+1) - \sigma^2\}$$

An analysis of the bands shows that the terms fit this form provided j is given integral values This is as it should be according to Mulliken's theory, if the emitting molecule is that of neutral H_2 (odd multiplicity) The lowest lines are R' (0), Q (1), and P' (2), which shows that σ'' is zero in the final terms, as we should expect for an S state

While the major part of the term is clearly of the form just given, a preliminary examination of the term differences showed that an appreciable 'correction term' in the fourth power of j (or j_k) is present. Such a term is to be expected on the old theory Unfortunately, no general expansion for the band terms on the new theory is available At the sug-

gestion of Prof H S Allen, the following tentative term-formula was adopted

$$F(j) = \Sigma X_n\{j(j+1) - \sigma^2\}^n, \; n = 1, 2,$$

Here in the usual notation, $X_1 = B$, $X_2 = D$, In using this formula we need only take into account as many terms as are likely to be required Actually, we may obtain a good fit for the hydrogen bands by taking into account only the first two terms ($n = 1$ and 2) Such a two term formula has in fact been found to give a good fit for bands consisting of a large number of members in the case of the blue green bands of Na_2 ($^1P \longrightarrow {}^1S$) described by Loomis and Wood

A least square determination of the constants of the Fulcher null band ${}_2a_0$, taking into account the first four terms of the above formula, yields the following values for the final constants

$$B'' = X_1'' = 33\ 38879 \quad \text{cm}^{-1},$$
$$D'' = X_2'' = -0\ 0229274 \quad \text{cm}^{-1},$$
$$X_3'' = \ 4\ 8565 \times 10^{-5}\ \text{cm}^{-1},$$
$$X_4'' = -3\ 1250 \times 10^{-7}\ \text{cm}^{-1}$$

The initial constants agree in sign and magnitude with the above Moreover, the two values of B' obtained for the initial state one for the Q branch and the other for the P' and R' branches, differ sufficiently to allow the initial constant σ' to be determined within narrow limits Its value comes out as $\frac{1}{4}$, the actual determination being 0 2506 This result is curious, and points to some, as yet unexplained, peculiarity of the term form

With this value of σ' we obtain

$$B_A' = 29\ 60537 \text{ cm}^{-1} \text{ for the } Q \text{ series}$$
$$\text{and } B_B' = 29\ 84408 \text{ cm}^{-1} \text{ for the } P' \text{ and } R' \text{ series}$$

It may be pointed out that in the case of the $^1P \longrightarrow {}^1S$ bands of Na_2 these constants only differ by 0 00001 cm $^{-1}$ Thus, hydrogen seems to present possibilities for band analysis which are lacking for the heavier molecules

It is hoped to discuss the Fulcher bands in greater detail in a future communication

The Angular Distribution of Compton Recoil Electrons

Up to the present the 'intensity problem' of the Compton theory has remained unsolved Many hypotheses have been put forward, and there exist two different solutions based on the new quantum mechanics, experiment, however, has not given any definite decision in favour of either solution

There are two ways of experimental test the investigation of the angular distribution of the secondary quanta (scattered radiation), or the study of secondary recoil electrons In both cases the decisive information may be obtained only by using very hard rays, that is, γ rays Wilson's cloud expansion method presents essential advantages in this respect The spectral distribution of the secondary β rays emitted under the recoil angles $\delta < 20°$ is known from my measurements published in 1927 (*Zeit f Phys*, B **43**, 354) More detailed data were reported at the conference on β and γ ray problems (Cambridge, July 1928) These data enable one to determine the corresponding statistical weights of the different spectral components of the inhomogeneous radiation used for each given distribution examined The results of this comparison are thus independent of the supposed distribution of intensities in the primary spectrum, this supposition in most cases being based on very untrustworthy data taken from an outside series of observations

In the following table the angular distribution of a thousand β ray tracks measured in the course of the last one and a half years (observed in the gas under the action of a narrow beam of γ rays filtered through 3 5 mm of lead) is compared with the results of calculation according to three different theoretical formulæ In each individual case the recoil angle has been determined with sufficient accuracy by measuring Wilson's photographs on Pulfrich's stereo comparator The figures enclosed in brackets in the column of observed values correspond to three separate series of measurements, including 408, 298, and 305 tracks each The figures belonging to the first series are reduced in the proportion of 300 408 The comparison with the data supplied by the latest theories of Dirac–Gordon and Klein–Nishina is also shown in a diagram (Fig 1) The areas limited by separate parts of the broken lines are proportional to the calculated number of electrons in the corresponding intervals, the circles giving the observed values of the mean ordinates for the same intervals

Numbers of recoil electrons in different angular intervals

	Observed		Calculated according to					
			Klein Nishina		Compton		Dirac Gordon	
		n_0	n	$\frac{\lvert n_1 - n_0\rvert}{n_1}$	n_2	$\frac{\lvert n_2 - n_0\rvert}{n_2}$	n_3	$\frac{\lvert n_3 - n_0\rvert}{n_3}$
0°–10°	39, 34, 44	117	92	0 27	72	0 62	48	1 44
10°–20°	48, 54, 47	149	152	0 02	148	0 01	93	0 60
20°–40°	76, 81, 85	242	266	0 09	264	0 08	280	0 14
40°–60°	75, 66, 74	215	224	0 04	230	0 07	287	0 25
60°–80°	56, 55, 50	161	146	0 10	162	0 01	171	0 06
80°–90°	6, 8, 5	19	20	0 05	26	0 27	22	0 14
			$\frac{\overline{\lvert n_1 - n_0\rvert}}{n} = 0\ 095$		$\frac{\overline{\lvert n_2 - n_0\rvert}}{n_2} = 0\ 177$		$\frac{\overline{\lvert n_3 - n_0\rvert}}{n_3} = 0\ 44$	

Klein and Nishina's letter (Nature, **122**, 398, 1928) contained a comparison of the intensity curves of scattered radiation calculated on the three theories mentioned above In this case the curves differ considerably only in the region of large scattering angles, where the intensities of the scattered rays are extremely weak, therefore any definite decision in favour of either curve is scarcely to be expected. The observed angular distribution of the secondary electrons, however, diverges from Dirac–Gordon's curve to a large degree and is definitely in contradiction to their theory

Of all the three theoretical results compared above, Klein–Nishina's formula is in the best agreement with our data The discrepancies, however, exceed even in this case the probable statistical deviations These discrepancies also cannot be attributed to experimental errors only We are evidently confronted with systematic deviations, which will be shown more clearly in a detailed paper shortly to be published

The question of the angular distribution of secondary radiation is intimately connected with the problem of the determination of the scattering absorption coefficient as a function of wave length This relation is implicitly contained in the formulæ of Dirac–Gordon and Klein–Nishina, which determine the above distribution

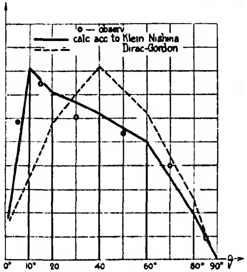

FIG 1 —Distribution of recoil electrons

The result of the comparison quoted above can be therefore considered as a serious argument against the scattering absorption formulæ deduced by Dirac and Gordon, as well as against the estimations of the wave length of ultra γ rays based on this deduction

The Complexity of the K-β Line of X-ray Spectra

RECENT measurements of the X ray spectrum line $K\beta'$, and the separation of this line from the $K\beta_1$ line, make it remarkable that their separation had not been attained in the course of earlier measurements (M Siegbahn, V Dolejšek, *Zeit f Phys*, **10**, 159, 1922), especially in the case of elements of low atomic number, where the difference between $K\beta'$ and $K\beta_1$ is about 6 X U.

N Seljakov and A Krasnikov (*Zeit f Phys*, **33**, 601, 1925 NATURE, **117**, 554, 1926) distinguished the line $K\beta'$ for the element of atomic number 25 (manganese), and G Ortner (*Akad d Wiss Wien*, 1926 NATURE, **117**, 823, 1926) separated it in the case of some compounds of iron and cobalt These investigations show that only with certain compounds are these lines distinguished, and this has suggested to us that, in the case of lower elements, the diffusion of this line is dependent upon the state of chemical combination

We have now examined different manganese compounds with the object of determining this dependence, if possible, but within the limits of precision no relationship between the state of chemical combination and the breadth (diffusion) or displacement of the line has been found, and in all cases the $K\beta'$ line is readily distinguished (Fig 1)

The microphotometric curves of the lines from different compounds make it apparent that the ratio of the lines $K\beta_1$ $K\beta'$ becomes greater for oxides than for free elements, in which case it coincides with the results of Seljakov and Krasnikov The value of this ratio, in the investigations of Seljakov and Krasnikov, is found to be 2 1 The determination of the value of the intensity ratio from our measurements is not considered here, this is being investigated independently with J Hrdlička, and the results will be presented in due course

Although we could not ascertain, within the limits of our measurements, any influence of the chemical combination on the displacement of the lines, we

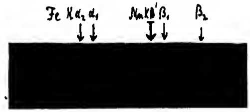

FIG 1

cannot say that it does not exist Such quite small influence could manifest itself with the compounds—which are not stable on the anticathode—by the diffusion (broadening) of the lines To eliminate such possible source of error, we used only the free metals for our measurements of the $K\beta'$ line of other elements

The measured differences of this line from the $K\beta_1$ line are shown in Fig 2

The curves (a, a) in this Fig show also the different breadth of this line $K\beta'$ in the case of different elements For the lower elements the breadth is greater —twice greater—than that of the $K\beta_1$ line With these elements we have found that the $K\beta'$ line is two

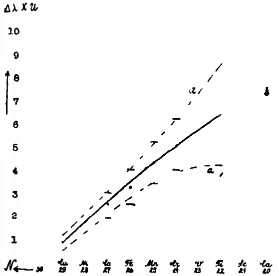

FIG 2.

unresolved doublet lines, which in the case of the higher elements are superimposed As is well known, the difference Δλ between the $K\beta'$ and K-β_1 increases with the decreasing atomic number As one can see from Fig 2, the breadth of the line increases simultaneously with the decreasing atomic number That is the reason why it is so difficult to distinguish $K\beta'$ with elements of lower atomic number (Δλ = c 6 X U) as compared with those of higher elements (Δλ = c 2 X U)

We have measured, separating this line in all the

elements mentioned, the difference $\Delta\lambda$ from the middle of the lines contrary to our previous measurements of the edges of the emission bands Therefore we can determine quite surely the energy frequency difference $\Delta\nu/R$ of the $K\ \beta_1$ and $K\ \beta'$ This difference of frequency resulting from our measurements $\Delta\lambda$ does not coincide with the values calculated from the frequency differ ences of the M_{II} and M_{III} levels, and consequently these two lines cannot both be due to transition $K \longrightarrow M_{II}$, $K \longrightarrow M_{III}$, in agreement with the opinion of G Ortner (*l c*) and D Coster and M F Druyvesteyn, (*Zeit f Phys*, **40**, 735, 1927)

Further, from our measurements we can see, by following the course of the $\Delta\lambda$ of these lines, their dependence on the atomic number (Fig 2), that there is no peculiar change in the region of the iron family

In conclusion, we consider that the $K\ \beta'$ is a complex line, and it is impossible to arrange the line in the scheme of Bohr and Coster The origin of this line is as yet unknown

Diœcism in *Ranunculus acris*

DURING the course of a cytological investigation of the reproductive organs of diœcious and intergrade forms of *Ranunculus acris* L, in connexion with the genetical work of Mr F M Marsden Jones and Dr W B Turrill, a matter of some general interest has arisen, which it is thought advisable to put on record forthwith

Examination of a hermaphrodite flower showed that there are two distinct and successive phases in the development of the flower first, a male or anther phase, marked by the commencement of physiological activity in the tapetum, and continuing until the formation of mature pollen grains, and secondly a female or ovule phase, commencing with the growth of the ovules and continuing until the formation of mature embryo sacs This development of male and female tissues in successive phases is the normal arrangement in hermaphrodite flowers, the interval between the two reduction divisions being constant for any given species, the variations between different species being correlated with the amount of ovular development therein

In the flowers of a 'female' plant of *R acris* the male and female phases coincide completely, the reduction divisions in anthers and ovules commencing at the same time The two processes are not able, apparently, to proceed concurrently, and complete failure of the tapetum in the anthers is probably due to lack of sufficient food supplies reaching them from the main axis

Several of the forms of *R acris* intermediate between 'normal hermaphrodite' and 'female' were also examined, and there was found to be a direct correlation between the extent of overlap of male and female phases on one hand, and the amount of good pollen produced on the other In each case the commencement of growth in the ovules was associated with the sudden failure of the tapetum in the anthers of the same flower, with cessation of pollen develop ment as a sequel

It is conceivable that this time factor will explain the occurrence of complete and partial diœcism in many species, in those plants where all grades from staminate to pistillate flowers are found, there are indications that the appearance of partial or complete 'male' forms, with a corresponding sterility of the ovules, may be explained by variations in the vascular structure of the flowers under consideration

A detailed account of the influence of this time factor in *R acris* and some other species is being prepared for publication

Floating Mercury on Water

WHILE trying, recently, a process for cleaning mercury, I obtained some small globules floating on water, in the same way that a waxed needle floats The mercury had been shaken with sulphuric and chromic acids, and was finely subdivided, on pouring carefully into water, a few globules floated Some of these ran together and coalesced in deep depressions in the surface the largest floating globule was about 0 5 millimetre diameter The flotation was quite

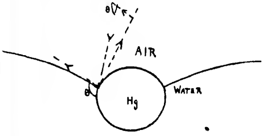

FIG 1

stable and was not destroyed even by contaminating the surface with a drop of oleic acid, which spreads to a film reducing the surface tension to about 46 dynes per centimetre The accompanying rough sketch (Fig 1) shows the directions of the relevant surface tensions dotted in

The tensions of clean mercury against air (475 dynes per centimetre) and against water (375) differ by more than the surface tension of clean water, so that it would be impossible for clean mercury to float on water, the water would spread over the whole drop with zero contact angle It is, however well known not to be easy to get mercury clean enough for water to spread on it The condition of flotation is that the contact angle θ, should be definite and for stable flotation it should be large The mercury air tension must be reduced to well within 46 dynes per centi metre of the mercury water tension, for flotation on the surface contaminated by oleic acid Since the mercury had been emulsified in the mixed acids probably even the mercury water tension had been a good deal reduced, therefore the mercury air tension seems to have been reduced by an amount of the order one or two hundred dynes per centimetre

I have never seen a description of the floating of mercury, and should be interested to hear if there is any record of it, or if anyone else has observed it

The Electric Moment of Primary Alcohols

OF late the question of the permanent dipole moment of polyatomic molecules has been considered of great importance in order to elucidate the nature of forces that interact between the constituent atoms of the molecules

The electric moments of a number of primary and secondary alcohols have been determined in this

laboratory by Mr P C Mahanti and Mr R N Das Gupta with the Nernst bridge method, and the results clearly indicate that, so far as the *primary* alcohols are concerned, they have practically the same dipole moment in them

Since these alcohols are produced by the substitution of one atom of hydrogen by an OH group in the normal hydrocarbon molecules, it is reasonable to infer that the dipole moment is due to the polarisation of the oxygen atom by the hydrogen atom on one hand and by the carbon atom on the other In other words, it may be stated that the binding forces acting on the carbon atom reacting with the oxygen are just the same whether the chain is long or short, open or closed It may also be pointed out that the carbon atoms associated with the CH group forming the iso alcohols have quite different binding forces leading to different values of the permanent dipole moments The details of the investigation will be published elsewhere

Action between Copper Salts and Glycerol

A VIGOROUS action occurs when a solution of any of the copper salts (hydrated or dehydrated) in glycerol is heated to about 150° to 200° C

The salts, with the exception of cupric chloride, are invariably decomposed into metallic copper (fine powder more than 99 per cent pure) and free acid, which may also undergo further decomposition The decomposition products of glycerol are ethyl alcohol, acrolein (when the salt acts as a dehydrating agent), carbon dioxide, methane, carbon monoxide, and hydrogen, the last two being present only in small quantities

With cupric chloride instead of metallic copper a white precipitate of crystalline cuprous chloride is obtained This may be regarded as due to a secondary action set up in presence of copper, hydrochloric acid, and cupric chloride which is still in solution The action seems to be fairly general, as other polyhydroxy alcohols (glycol, erythritol, and mannitol) give nearly the same result

It is known (Sabatier and Gaudion, *Compt rend*, **166**, 1033 1039, 1918) that glycerol vapour is decomposed into almost the same products mentioned above, at 330° C, in presence of finely divided copper It is very likely, therefore, that in the present case a proportion at least of the decomposition products are due to the catalytic action of copper

If, as is generally believed, metallic salts dissolve in polyhydroxy compounds, replacing the hydrogen of the hydroxyl group by the metal, copper and glycerol would form a compound of the formula: $C_6H_{10}O_6Cu_3$ Further, as copper, carbon dioxide, and methane are the chief products of the reaction a possible way of explaining it would be: $C_6H_{10}O_6Cu_3 = 3Cu + 3CO_2 + CH_4 + C_2H_6$, although there is no direct evidence of ethane

Apart from the theoretical considerations the reaction gives a method for preparing pure, finely divided copper, which is very suitable for catalytic purposes Even crude copper sulphate yields quite a good product The method may be also employed for preparing cuprous chloride from cupric chloride, the reduction being quantitative

A detailed paper on the subject will be published shortly

Effect of Electric and Magnetic Fields on the Helium Spectrum

(BY IMPERIAL WIRELESS SERVICES)

WITH a nearly uniform magnetic field of fifteen thousand gauss perpendicular to an electric field which varies from zero to fifteen thousand volts per centimetre, I find many lines which are not ordinary Stark components and appear not to be due to impurities Effects are similar in the corresponding parhelium and orthohelium line groups near the diffuse series lines For example, strong lines appear on the violet side of 4388 A and 4026 A at distances nearly double those of the usual fundamental combination lines of the Stark effect These well defined lines show no decided polarisation, and at maximum field are displaced toward the red 0 5 A and 0 2 A respectively At an intermediate value of electric field, components in 4026 group are displaced from the diffuse line 0 25 A, 0 47 A, 0 62 A, 0 78 A, 1 90 A, 2 10 A The components in positions of usual Stark components of large displacements are relatively diffuse

That new lines should appear in the presence of crossed fields was first stated by Prof Bohr It is now possible to make repeated observations on these, owing to experimental features which will be described in a later paper

In this research, I have been assisted by Dr Chalk through a grant from the National Research Council of Canada

The Transvaal Fossil Human Skeleton

By Dr ROBERT BROOM, F R S

AT the end of January last a road party, working in the Springbok Flats about eighty miles north of Pretoria, in excavating calcareous ground to make a road, came across a human skeleton and bones of the extinct buffalo (*Bubalus Bainii*) and of a large antelope The spot where the bones were found has been visited by Mr C J Swierstra of the Transvaal Museum and Mr Herbert Lang, and they have taken careful observations of the occurrence There is a foot and a half of dark reddish-brown surface soil, with below it about six feet of calcareous tufa (Fig 1) The skeleton was obtained at a depth of three feet from the surface and thus about one and a half feet from the top of the tufa The bones are for the most part much impregnated with lime and, except the powerful long bones, badly broken The skull is mostly broken into pieces about the size of half a crown or smaller, but fortunately the mandible is well preserved In the opinion of Mr Lang, the man has probably been killed while hunting and his body crushed in the mud by the trampling of a wounded buffalo—not improbably the one whose bones lay near his own Mr Swierstra has kindly asked me to make an examination and report on these bones

FIG 1 —The quarry where the human remains were found Mr Miller who discovered the remains, is pointing to the layer in the tufa where the bones were found

The fitting together of the cranial fragments has been a matter of some difficulty, as at present about a quarter of the fragments are missing, and most are so impregnated with lime that it is difficult getting them sufficiently cleaned to fit nicely Still, enough has been done to give a satisfactory idea of the shape and general character of the skull

The Transvaal Museum is at present at work going over all the ground to endeavour to obtain all the missing fragments As this will take a considerable time and will not alter materially any conclusion that can now be come to with regard to the skull, there seems nothing to be gained by delaying, more especially as the press has been largely interested in the matter and has been issuing reports, some of which are not altogether correct

At present we have almost the complete right side of the skull and much of the left side, but without the basicranial region, and the whole of the face except the frontals and malars is lost The mandible is practically complete Of the post cranial skeleton there are remains of three vertebræ and fragments of many ribs, a fragment of one scapula, half of one clavicle, both humeri but with the ends lost, much of both radii and ulnæ, and much of one hand There is no trace of the pelvis or sacrum, but both femora are well preserved except that the ends are lost, and there is much of both tibiæ and parts of the fibulæ, with a well preserved astragalus

The skull is of the modern type with a fairly large brain The maximum length is about 195 mm and the breadth is about 144 mm The antero posterior measurement can be relied on as very nearly accurate, but the breadth is less certain, as the fragments of the left side of the skull cannot at present be fitted together, but the greater part of the occiput and frontales are preserved, and the middle line can thus be approximated The cephalic index is thus about 74 The frontal region slopes, as seen on the photograph (Fig 2), and is not in the least Neanderthaloid The frontal bone is narrow, the width at the lower part being about 106 mm The parietal region is lower than in most modern types of man, and there are no marked parietal eminences The bones are not unduly thick—the maximum being less than 9 mm

The mandible is unusually long and very massive, and there is a well marked chin (Fig 3) The ascending ramus is very wide, being 48 5 mm from the front of the coronoid process to the hollow below the condyle From the condyle to the front of the symphysis is about 141 mm The symphysis is 17 5 mm in thickness The teeth are

relatively small, the three molars measuring only 30 mm and the molars and premolars together 42 mm The crowns are badly worn down, and the pattern cannot with certainty be determined There seems, however, to be no clear evidence of a 5th cusp, except perhaps in *m* The under side of the symphysis resembles considerably that of Neanderthal man The angle of the jaw is extremely thick (7 8 5 mm) and has prominent muscular ridges

The limb bones are large and powerful I estimate the humerus to be about 330 mm long, but as both ends are lost it is impossible to give the measurements quite accurately The radius ulna and phalanges are all those of a powerfully built man

The femur can be restored with much probability only the head and the distal end being unknown There is considerable resemblance to the thigh bone associated with the Rhodesia skull The bone is very long and massive the greatest length is as near as may be 500 mm The shaft measures below the lesser trochanter 36 mm by 28 mm The shaft is very considerably curved The tibia is about 435 mm in length and the shaft near the nutrient foramen measures 40 mm by 30 mm

A comparison with previously known prehistoric human skulls at once suggests a possible affinity with that of Cro Magnon man and with the previously known large brained South African fossil type the Boskop man The present skull which may be referred to as the Bushveld skull resembles both in being large brained and in having a fairly good forehead and quite small supraorbital ridges The man was also like that of Cro Magnon,

Fig 2 —Skull of Bushveld man as restored by R Broom

of large stature But there are some points of striking difference Cro Magnon man had a high parietal region Bushveld man has, like the Hottentots and Bushmen a relatively low parietal region This is a point to which most anthropologists pay little attention, but it is in my opinion one of very great importance Lowness of the parietal region is evidently a primitive character It is found in *Pithecanthropus*, *Eoanthropus*, Neanderthal man, Rhodesian man, and in Boskop man and in the Bushman of to day In Cro Magnon man, as in most living races, the parietal region is high There are many other striking points of difference, though possibly Cro magnon man may be descended from a Bushveld like type

Boskop man also has some points of likeness Both have low parietal regions, but there are few

Fig 3 —Under side of jaw of Bushveld man with jaws of a Kaffir and a Hottentot for comparison

other resemblances Boskop man has prominent parietal eminences Bushveld man has not Boskop man has parietals 15 mm in thickness The skull of the Bushveld man is nowhere more than 9 mm The teeth of Boskop man have apparently been large those of Bushveld man are small The bones of the Boskop man are much more completely mineralised and probably older but until a good skull is obtained it will be impossible with certainty to fix its position

The Bushveld man was certainly the contemporary of the extinct *Bubalus Bainii* At Hagenstad, in the Orange Free State, we have many human implements in association with the bones of not only *B Bainii* but also of the extinct *Equus capensis* and of two large extinct antelopes We are thus probably justified in assuming that the Bushveld man was a member of the race that made the Hagenstad type of implements These implements according to the archæologists, are regarded as representative of the middle old stone age of South Africa and we may thus regard the Bushveld man as the man of the middle Palæolithic period Of course, at present we are quite unable to date the remains in years We can only say that they are certainly very old

There are many reasons for regarding the Korannas a few of whom still survive in South Africa, as the direct descendants of the Bushveld type of man For many years I have regarded the Korannas as one of the most important of the surviving races, though hitherto anthropologists have given them very little consideration From the enormous numbers of implements found in the diamond gravels there must have been a powerful race numbering tens if not hundreds of thousands, inhabiting the Vaal River valley in prehistoric times This Bushveld skeleton is the first evidence we have of a man that probably belonged to this race, and it is interesting to find how closely he agrees in many respects with the surviving Korannas of to day

Chemiluminescence [1]

By Dr ERIC K RIDEAL

IN attempting to make the subject matter of this discourse as experimental as possible, it will be impossible to delve in great detail into the molecular mechanism of the reactions This, I think, is as well, because many of the reactions which should be shown on account of their great beauty are certainly extremely complicated and have not, in fact, been subjected to any but a very superficial examination

Chemiluminescence may be regarded as the counterpart of photochemical processes By the absorption of light of suitable frequencies atoms and molecules may be raised to states of higher initial energy These excited entities may now undergo a series of changes, the nature of which will depend on a variety of circumstances They may liberate their absorbed energy in the form of fluorescent light, impart part or all of their energy to a neighbour of another species by a collision, become converted into a metastable more permanent and energy rich molecule which may afterward revert to the normal form, or suffer some species of chemical reaction such as ionisation dissociation, or combination

By suitable modification of conditions one can affect the velocities of chemical reactions over relatively wide ranges, and it is found that in many strongly exothermic reactions there exists a narrow range of relatively high velocities which is chemiluminescent Closer examination indicates that practically all these reactions are complex in that they are accompanied not only by the emission of radiation localised in some portion of the spectrum but also by a rise in temperature It is by a study of the chemiluminescent portion of such composite reactions that we may hope to gain a further insight into the molecular mechanism and the operation of the process of chemical activation

We may with some degree of assurance assume that chemiluminescence is in many cases the result of liberation of chemical energy in a form similar to that of fluorescent energy, and we have noted that fluorescence is the result of decay of a number of excited molecules, the excitation being produced in this case by the absorption of radiation Thus conditions suitable for chemiluminescence result in reactions in which large numbers of excited molecules are produced by chemical reaction, under conditions such that at least a fraction of the excited molecules can revert to the normal form with the emission of radiation Excluding thermally accelerated exothermic reactions, a large group of auto accelerating reactions exhibit chemiluminescence, these are usually designated as branching chain reactions, and we shall observe that there are several hypotheses as to the nature of such reactions and at least two distinct light-producing processes

A typical reaction of this type is the oxidation of phosphorus—one of the oldest chemiluminescent reactions observed with a definite substance, although the chemiluminescence of fireflies, decaying wood and certain bacteria and fish have long been commented on and were formerly attributed to the action of vital forces The name phosphorus arose from a confusion of chemiluminescence with the phosphorescence of the impure barium sulphide, the so called lapis Bologniensis We may symbolise the fact that the reactions proceed in branching chains in a number of ways thus, denoting the reactants by A_2 and B_2 and the molecules in the excited state by A_2, we might postulate as the mechanism

$$
\begin{aligned}
(a)\quad & A_2 + B_2 \longrightarrow A_2B_2 \longrightarrow (AB)_2 \longrightarrow AB + AB \\
& AB + A_2 \longrightarrow AB + A_2 \\
(b)\quad & A_2 + B_2 \longrightarrow AB + A + B \\
& A + B_2 \longrightarrow AB + B \\
& B + A_2 \longrightarrow AB + A
\end{aligned}
$$

In both cases the conditions that one elementary reaction shall produce at least two reacting molecules so as to effect an auto accelerated reaction are fulfilled, but whilst in the first the chemiluminescence is imagined to result from the return of the excited species AB or A_2 to the normal in the second it is supposed to take place through some type of atomic combination, for example $2A \longrightarrow A_2$ or $A + B \longrightarrow AB$, a mechanism which has been more fully investigated in a series of reactions which will be discussed later

We may note that in addition to these types of chain mechanism there exists a third in which it is imagined that a certain number of reaction centres are formed by some identified as ions, around these reaction centres reaction takes place and more reaction centres are formed As a hypothetical case we might imagine that in a hydrogen chlorine mixture a positive ion is formed and around this ion a number of hydrogen and chlorine molecules are held by electrostatic forces On neutralisation of the ion the energy set free effects the combination of the small group of molecules around the ion and chemiluminescence and the formation of a few more ions result

That in the oxidation of phosphorus, sulphur, and probably many other substances the chemiluminescence is the result of some such type of chain mechanism can scarcely be doubted, but it is difficult in fact to state to which of these three possible types any one reaction definitely belongs It is perhaps significant that in the oxidation of phosphorus a number of the lines in the complex band spectrum of the emitted light are identical with those of ionised oxygen A typical phenomenon observable in the chain or cluster reactions is that of inhibition by small quantities of inhibitors We may note the ease with which inhibitors such as benzene and ether inhibit the glow of phosphorus, a confirmation of the nature of the chemical process at work Many other vapours exhibit chemiluminescence on oxidation, a fact noted by Sir Humphry Davy, thus the vapours of ether and carbon disulphide can readily be caused to undergo cold luminous combustion Under more restricted

[1] From a lecture with experiments, delivered at the Royal Institution on Friday, Feb 15

conditions, the union of acetylene and chlorine and the oxidation of the hydrocarbons can be made to exhibit chemiluminescence, and although in these reactions the thermal changes are relatively large, yet since the light emitted is definitely chemiluminescent it seems almost certain that, contrary to the views of several investigators in these reactions, one cannot be dealing exclusively with thermally accelerated as opposed to branching chain or cluster accelerated reactions, excited molecules atoms, or reactive clusters must be taking part in the reaction

Far more complicated, but equally beautiful, are a number of chemiluminescent reactions taking place in solution The well known Wedekind reaction, the interaction of chlorpicrin and phenyl magnesium iodide exhibiting a green chemiluminescence, requires the use of a draught chamber, but the cold oxidation of pyrogallol formaldehyde mixture exhibiting an orange red light, due to Trautz and Schorigin, blue luminescence in the oxidation of 3 aminophthalic hydrazide and the green of tri phenyl glyoxalin (Lophin) are all brilliant and readily demonstrated These reactions are characterised by a high temperature coefficient—some 2 3 for a rise of 10° C —an indication of the chemical origin of the light emitting system

It is somewhat remarkable that few people have observed the beautiful chemiluminescence exhibited by the interaction of chlorine or chromyl chloride with ammonia, although I suppose the former reaction is demonstrated annually in at least one of the classes in every school where chemistry is taught

Sir James Dewar noted a chemiluminescence when ozone is brought into contact with organic matter Such chemiluminescence is particularly marked in the oxidation of certain dyestuffs both fluorescent and non fluorescent, we may observe the phenomenon in a brilliant form in the case of alcoholic solution of both eosin and safranin The chemiluminescent light is not identical with the fluorescent light of these dyes This reaction may be modified so as to give a very vivid demonstration of the action of inhibitors By addition of a small quantity of hydroquinine to the alcoholic solution of safranin we note that on exposure to ozone no chemiluminescence results, the dyestuff is not oxidised, but after a minute or two the hydroquinine is completely oxidised and the brilliant green glow of the dyestuff undergoing oxidation spreads over the bulb

We have already indicated the possible connexion between chemiluminescence and reversed photochemical action, postulating in both cases the generation of an excited molecule formed in the former by chemical and in the latter by radiant processes This analogy may be pursued somewhat further by a consideration of the mechanism of photochemical sensitisation and its reversal In cases of photochemical sensitisation, a molecule excited by the absorption of radiation conveys by collision part or all of its energy to a molecule of another species which afterwards undergoes chemical reaction The beautiful experiments of Franck and Cario in forming chemically reactive hydrogen by sensitisation with mercury vapour excited by the line $\lambda 2537 \cdot 4$ A may be cited as a case of photochemical sensitisation A similar complementary reaction in chemiluminescence has been observed by Kautsky, who showed that the energy liberated as chemiluminescence in the oxidation of the suboxide of silicon, siloxene, could be transferred to certain dyestuffs causing them to become excited and undergoing fluorescence Only those dyestuffs such as fluorescein and eosine which are adsorbed by the crystals of the siloxene can be made to fluoresce, an indication that the energy necessary for excitation of the dyestuff molecule must be transmitted by collision from one of the surface molecules of the solid reacting siloxene, which in turn must pass through the stage of an excited molecule during oxidation

The experiments initiated by Haber and Zisch on the interaction of the alkali metals with halogens and halides have more recently been re examined by numerous investigators, notably Kondratjew, Ljalikoff, and Polanyi, these all exhibit beautiful chemiluminescent effects The interaction of sodium and iodine vapour and of potassium and iodine demonstrate the various phenomena to be observed in these reactions, and analysis of the radiation, as well as of the distribution on the tube walls of the salt formed, gives us a clue to the mechanism of the reaction In the interaction of sodium vapour and iodine we may compute the thermal changes accompanying all the possible reactions

$$
\begin{aligned}
&(1)\ Na + I_2 = NaI + I + 33 \cdot 5\\
&(2)\ Na + I = NaI + 68 \cdot 7\\
&(3)\ Na_2 + I = NaI + Na + 51\\
&(4)\ I + I = I_2 + 35 \cdot 2
\end{aligned}
$$

It is observed that the D line only is emitted, corresponding to a chemiluminescent emission of 48 3 cal Of the four reactions listed above, only two are accompanied with sufficient energy for the liberation of the D line, namely, (2) and (3) A further observation that the chemiluminescence possesses in this case a negative temperature coefficient, suggests that only one of these reactions, namely, $Na_2 + I = NaI + Na$, is responsible for the chemiluminescence observed in the gas phase, and that neither (2) nor (4) takes place in the gas phase except in a reaction more involved than a bimolecular one The tube walls catalyse both reactions (2) and (4) effectively The surface catalysed reaction is clearly observed in the union of potassium and iodine, for the reaction (3) above does not occur to an appreciable extent when sodium is replaced by potassium on account of the low concentration of diatomic potassium molecules in the vapour of the element

The bulk chemiluminescent processes can accordingly be represented as

$$
\begin{aligned}
&Na_2 + I \rightarrow NaI' + Na\\
&NaI' + Na \rightarrow Na' + NaI\\
&Na' \rightarrow Na + h\nu
\end{aligned}
$$

Chemiluminescent methods may be employed not only to identify as noted above the nature of

the molecular processes involved in a chemical reaction, but also to fix, within certain limits at least, the energy of dissociation of certain gases Thus, the simple dissociation process,

$$H_2 \rightleftarrows 2H,$$

in reality must be much more complicated in operation than the unimolecular bimolecular dynamic equilibrium postulated by this equation given in the text books Whilst the efficiency of collision in causing reaction of complex molecules such as $2NO_2 \rightleftarrows N_2O_4$ is usually high, that of atomic recombination is very low, and if we regard a pair of normal atoms in close proximity to one another as the extreme case of dissociation, the absence of an electric moment in the system forbids the quantised emission of radiation Thus reactions such as $2H \rightarrow H_2$, $2Br \rightarrow Br_2$, only occur in the presence of a third body or a surface, and the energy of combination transmitted to the third body is frequently emitted as chemiluminescence, a phenomenon readily observed with atomic hydrogen The energy of combination of atomic hydrogen is found to be sufficiently great to excite the OH molecule to emission, but not the mercury line λ2537 A in mercury atoms, this places the energy of dissociation of hydrogen between 94,000 and 112,000 cal per gram molecule

Atomic hydrogen, readily prepared by Wood's method, is a convenient source of many chemiluminescent experiments The afterglow of a number of gases, notably oxygen, nitrogen dioxide and nitrogen, when excited by the electric discharge, may all be regarded as chemiluminescent reactions in that the gases possess enhanced chemical reactivity in the glowing state The glow of nitrogen dioxide and nitric oxide and the after glow of Lord Rayleigh's active nitrogen are particularly brilliant, but the chemical processes involved are at present obscure It seems at least definitely established that active nitrogen contains at least two chemically reactive species, both atoms and excited molecules The cohesion of solid surfaces may be regarded as a species of chemical reaction in the solid state, and several of these reactions are found to be chemiluminescent, although frequently classified as tribo or crystalo luminescent reactions, the crystallisation of arsenious oxide and sugar exemplify this class of reaction

Other quasi chemical reactions which are luminescent include the fluorescence and phosphorescence excited in various substances, especially in solid solutions, by electron bombardment, some of the effects produced by the bombardment of minerals such as kunzite by high speed electrons being particularly brilliant Finally, we may observe the chemiluminescence obtained with certain bacteria such as *B fluorescens* and the reaction between luciferin and luciferase, the basis of biological light

Obituary

MR S S BUCKMAN

THE son of Prof James Buckman, a well known botanist and geologist of his day, Sydney Savory Buckman, born in 1860, early followed in his father's footsteps His attention was particularly directed to the Brachiopoda and Ammonites of the Inferior Oolite, and so early as 1883 he contributed a paper on the former to the *Proceedings of the Dorsetshire Natural History Field Club* Buckman will, however, be chiefly remembered for his work in connexion with the Ammonites, which he showed could be used as zone fossils for subdividing the Jurassic strata His study of these was extensive, and a monograph of those from the "Inferior Oolite Series" (never really completed) formed one of the Monographs of the Palæontographical Society (1887–1907), while he further traced their evolution through the successive strata, and in so doing was led to create a multitude of genera and species far beyond what had hitherto been deemed necessary

In connexion with all this work and subsidiary to it, Buckman published very many papers and memoirs on the classification of Ammonites and Brachiopods When his connexion with the Palæontographical Society was severed, Buckman began in 1909 a work on "Yorkshire Type Ammonites," consisting of photographic figures of the types accompanied by the original descriptions This was carried on until his eyesight failed six months ago The geological structure of the Inferior Oolite also received his attention, and he traced foldings in the beds that in some cases corresponded with those known to exist in the underlying Palæozoic rocks, thus bearing out Godwin Austen's principle of the continuity of folding with its economic consequences

The physical geography of south western England was the subject of a paper (*Natural Science*, 1899) far too little consulted by later writers, in which Buckman treated of the "Development of Rivers, and particularly the Genesis of the Severn" The capture of the headwaters of the Thames by the Severn has, perhaps, never been better set forth Buckman's extensive and original work became absorbed to such an extent into contemporary geological thought that few of the younger generation of geologists realise how much they owe to him

The value of Buckman's labours was recognised by the Geological Society, of which he was elected a fellow in 1882, by the award of the Murchison Fund in 1897, of the Lyell Fund in 1903, and the bestowal of the Lyell Medal in 1913 His researches stimulated many a geologist, and not in England alone, to a more detailed study of the rocks and their fossil contents, and all such he was ever ready to help in the most unselfish way His death on Feb 26 last was greatly regretted by all privileged to know him, and his memory will be cherished as one of the kindest of men

DR DU RICHE PRELLER

DR C S DU RICHE PRELLER died at his residence in Edinburgh on Feb 17 in his eighty-fifth year He was a notable representative of a type of which the numbers are steadily growing less, to the great loss of the community A successful professional man, with varied interests rising naturally out of the practice of his profession, he superimposed upon those interests others which in the course of his long life led to his appearing to include most branches of knowledge within his sphere

By training an engineer, Dr Preller's technical training was supplemented by wide studies in pure science, carried out in French and German universities as well as in Yorkshire His active career was spent mostly on the Continent, where he was engaged especially in railway and electrical undertakings in Germany, Italy, and Switzerland, being at one time chairman and chief engineer of the Limmat valley electric railway He was also interested in the lighthouses of the French coast From his absorption in hydro electric installations there arose naturally an interest in problems of glacial geology and of mountain form and structure generally Again, an inborn aptitude for languages —he belonged to a Huguenot family long settled in England—combined with long residence on the Continent, made him an excellent linguist, he spoke and read easily French, German, Italian, and Spanish He had also a great love of music, art, and literature, while travel was another favourite recreation

Though Dr Preller collected together a number of studies on the geology of Italy in a book published in three volumes as "Italian Mountain Geology" (1918–23), for which the Royal University of Florence made him an honorary doctor of science, most of his scientific writings took the form of essays, papers, and letters contributed to technical, scientific, and other periodicals He was an occasional contributor to NATURE, but many of the papers of his later years, after his settlement in Edinburgh in 1912, appeared in the *Scottish Geographical Magazine* These dealt with a great variety of subjects, including the old problem of Hannibal's route across the Alps With interests so widely diffused great originality was not to be expected, and accuracy in detail at times left something to be desired, but for these qualities we look to the specialists The great importance of such men as Dr Preller is that they act as liaison officers between the educated public and scientific specialists Their steadily decreasing numbers is to be regretted in that the specialists are always tending to become more and more unintelligible even to their fellows in other branches

---

WE regret to record the death of Dr Humphrey Purnell Blackmore, widely known as an archæologist, which took place at Salisbury on Feb 2, at the age of ninety-three years He was educated at Queenwood College and qualified in medicine at the earliest possible age While in practice at Salisbury he took up the study of geology The results of his intimate study of local conditions were published in the Geological Survey account of Wiltshire He contributed to the Blackmore Museum, which was founded by his brother, a valuable series of palæontological remains which he himself had discovered in the local gravels When the Salisbury and South Wilts Museum was founded, now more than sixty years ago, it was very largely due to his activities, and he took a very considerable share in determining its methods and arrangement His interests in archæology were wide, and brought him into intimate touch with the most prominent archæologists of his day, among the more noteworthy being Sir John Evans, Sir Augustus Franks, Lord Avebury, and Sir William Boyd Dawkins Although to a later generation he was more widely known by name than personally, he was always ready to throw open the valuable collections in his house at Salisbury to research workers With his death, and that of Sir William Boyd Dawkins, has finally passed away that generation of pioneers which founded British prehistoric archæology and raised it to the foremost place in the study of the culture of early man

---

THE death is announced of Dr Joseph Goldberger on Jan 17 According to a *Daily Science News Bulletin* (Science Service, Washington, D C) he was born in Austria in 1874, and at the age of six emigrated with his parents to the United States Twenty years later he joined the U S Public Health Service and soon afterwards was attached to the Hygienic Laboratory, Washington His greatest contributions to science were his studies on the nature, cure, and prevention of pellagra, which he determined to be a food deficiency disease dependent upon lack of fresh and proper proteins He discovered that yeast is a preventive in the absence of fresh meat and milk He also contributed studies on yellow fever, dengue, measles, and influenza

---

WE regret to announce the following deaths

Mr Edward Davidson, for many years secretary and treasurer of the Royal English Arboricultural Society, on Mar 4

Dr Alex Hill, secretary of the Universities Bureau of the British Empire and formerly Master of Downing College, Cambridge, and Principal of University College, Southampton, on Feb 27, aged seventy two years

Mr John Hyde, from 1897 until 1905 chief of the bureau of statistics of the U S Department of Agriculture, known also for his work on the economic effects of disease, food and population, etc, on Jan 18, aged eighty years

Dr Frederic A. Lucas, director of the American Museum of Natural History from 1911 until 1923 and since honorary director, and a foreign member of the Zoological Society of London, on Jan 9, aged seventy-six years

Sir John Denison Denison Pender, G B E, K C M G, chairman of the Eastern and Associated Cable Companies, on Mar 6, aged seventy three years.

News and Views.

ON p 415 of this issue we publish the first authoritative account to reach England of the skeleton discovered in January last in the Springbok Flats, Transvaal The discovery has already been announced in cabled dispatches appearing in the English press, but the detailed account of the circumstances of its discovery and the results of the examination of the skeletal remains which Dr Broom now gives make it possible to form a more adequate estimate of its importance Its chief point of interest is that not only is the skull that of modern man, but it bears a close resemblance to the Cro Magnon type of the European upper palæolithic age In this it agrees with the Boskop skull, but another feature which it has in common with that skull and in which they both differ from the Cro Magnon is, that while the latter is high, they are both low This is important, as by some the Boskop skull was thought to have suffered from post mortem deformation The long bones of the new skeleton, though much broken, by the estimate of their length would bear out the resemblance to Cro Magnon man in point of being large The Bushveld skull, as Dr Broom suggests the new find should be called, resembles the Boskop skull in that the eyebrow ridges are not prominent and both are large brained Although not so long as the Boskop skull, to which an estimated length of 210 mm was given, the Bushveld skull measures 195 mm This, on an estimated breadth of about 144 mm, gives a cephalic index of 74 Although, as Dr Broom points out, the new skull differs from the Boskop skull in several particulars, it confirms the evidence of the earlier find of the existence in South Africa of an early large brained race But, whereas the Boskop skull was regarded as showing affinities with no existing race in South Africa, Dr Broom is inclined to see in the Korannas the descendants of Bushveld man

THE suggested correlation of the Bushveld man with the middle palæolithic of South Africa, through the association of the remains with an extinct species of buffalo also found in association with the Hagenstad type of stone implement, adds considerably to the interest and importance of the find This may be still further enhanced when it is possible to bring it more closely into relation with the investigations which Mr Leakey is carrying out in Kenya, where it is evident from the communication which appeared in the *Times* on Mar 7 that finds of a crucial character are possible at any moment The discoveries of this season which Mr Leakey announces are of a sufficiently surprising nature In last season's excavations at Elmenteita a Mousterian layer had been reached below the Aurignacian level in the cave known as Gamble's Cave II This year, two occupation levels with industries of typical Aurignacian facies have been found below the Mousterian horizon, belonging to the same Second Pluvial period as that horizon. This sequence has been confirmed at a number of sites As there is no evidence of any mingling of the Mousterian and Aurignacian industries, it can only be concluded that the Mousterian in East Africa represents an actual racial intrusion and not merely a cultural influence, while, further, the reversal of the sequence normal in Europe points to the immigration of a race from outside into an area in which the Aurignacian was either the indigenous culture or, at any rate, in which it was sufficiently near its place of origin to permit of its earlier penetration This is what might be expected on the view of the African origin of the Aurignacian culture Two skeletons have been discovered which agree with previous discoveries in associating *Homo sapiens* with Aurignacian industries Mr Leakey, holding that any human remains discovered in association with the Mousterian industry will be of the Neanderthal type, suggests that such remains may link up man in East Africa with Rhodesian man

THE centenary of King's College directs attention to an educational institution which has the distinction of being one of London's oldest colleges and the misfortune of being one of the poorest It is the worst endowed College in Great Britain, and yet the numbers of students have doubled since the War, and the high standard both of its teaching and research is being steadily maintained While the appeal for £350,000 which has been launched is wide, in that it embraces the improvement of buildings, the provision of endowments, scholarships, and bursaries, there is one particular aspect which we would recommend to our readers The College has always occupied a leading place in its work for scientific progress It was the first English college to establish either a physics or a bacteriological laboratory The work done in the physics and electrical departments is particularly distinctive Wheatstone invented the telegraph, Maxwell disclosed the principle to which broadcasting owes its origin, while in more recent times Prof O W Richardson formulated the laws underlying the action of wireless valve filaments Important wireless research is at present being pursued by Prof E V Appleton

THE electrical industry is largely indebted to work carried on at King's College The theory of the parallel running of electrical alternators as used to day in all the large power stations, and the invention of the three wire system of supply, were first propounded by Prof John Hopkinson The present professor of electrical engineering, Prof Ernest Wilson, has carried out important investigations on the corrosion of metals such as are used for overhead wires and are exposed to the London atmosphere Neither the physics nor the electrical engineering departments has an endowment income They are almost entirely dependent upon a fluctuating student fee income It is now proposed to raise a sum of £50,000 to endow chairs in these two departments The amount is modest enough in comparison with the wealth of the wireless and electrical industries, and donations to either branch of the College would be a recognition of indebtedness and an encouragement for future

research Donations may be sent either direct to King's College, Strand, W C 2, or to the College bankers, Messrs Coutts and Co, 440 Strand, W C 2

At the South Africa meeting of the British Association in July next, the Council will nominate Dr F O Bower, F R S, lately Regius professor of botany in the University of Glasgow, as president of the Association for the year 1930, when the meeting will be held in Bristol The Association has received from the Court of Common Council (the Corporation of the City of London) the expression of a hope that London will be selected as the place of meeting in the centenary year, 1931, and offering entertainment to the Association in that event This invitation has been accepted, and the centenary meeting will therefore be the first ever held in London

In view of the importance of the wool industry to South Africa, it is fitting that wool research should be a strong feature at the meetings of the British Association this year Among those who have already signified their intention of being present are Prof Aldred F Barker, head of the Textile Department of the University of Leeds, Dr S G Barker, Director of Research of the British Research Association for the Woollen and Worsted Industries, and Dr J E Nichols, also of the Research Association, who is at present engaged on a sheep and wool survey of the British Empire Principal H Richardson, head of the Technical College, Bradford, is also expected to attend Dr J E Duerden, Director of Wool Research of the Union of South Africa, will give an account of the wool investigations in progress in the South African Department of Agriculture, and others will deal with various nutritional and genetical experiments Mr E N S Warren, head of the Sheep and Wool Section at the Grootfontein School of Agriculture, will describe the instructional course given there, which is admitted to be one of the foremost in the world

The inauguration of a television broadcasting service in Great Britain is at present being considered by the Post Office officials Great progress has recently been made at the Baird laboratories and very satisfactory demonstrations of land line transmissions have been given on a 'televisor' It is quite easy to 'tune in' the picture by one control and 'frame' it correctly by the other control The pictures are still somewhat limited in size, but excellent 'head and shoulders' reproductions are given, and in conjunction with a loud speaker give a very interesting performance Considerable detail is given in the picture—the time, for example, on the performer's watch can be easily read A high tension pressure of 350 volts is required for the home televisor, but if an alternating current lighting supply is available, this can be readily obtained by an 'eliminator' At present the sets are designed for a fixed wave length of 200 metres (1500 kilocycles) It is, perhaps, too early to say what is the narrowest band of frequencies that is necessary to transmit a sufficiently satisfactory picture In the event of the establishment of a television broadcasting service, it would be advisable to have as narrow a band as possible so as to avoid interference with the ordinary broadcasting and other services Everything depends on how much flicker and lack of detail can be permitted without appreciably detracting from the pleasure of the 'looker on' Television for the theatre seems to be an easier problem than television for the home As this would be worked throughout by experts, the large performance factor of safety required for home sets would be unnecessary

In every continental area the number of wave lengths available for broadcasting is strictly limited The radiation from an aerial may be considered as made up of rays parallel to the surface of the earth and of rays inclined to the surface The latter radiations suffer very little attenuation, and, striking the conducting layer, get bent down towards the earth and sometimes produce interference with parallel waves Such interference has been noticed between stations 2000 miles apart In a paper by P P Eckersley and A B Howe, read to the Institution of Electrical Engineers on Mar 6, a method of getting over interference difficulties by using the same wave length for several stations is discussed Three other methods have been suggested The first is by securing a proper international agreement between the nations, the second by designing all transmitting aerials so that only radiations parallel to the earth's surface are emitted, and the third by using only a few high powered stations instead of many low power stations Most broadcasting authorities throughout the world are adopting the third of these methods In 1924, Captain Eckersley suggested in addition that several broadcasting stations in each country might be operated on the same wave length At the present time Edinburgh, Hull, Bradford, and Bournemouth share the same wave length with satisfactory results The case of Bradford is interesting, as it is only about 60 miles from Hull When Bradford shared a wave length with other European stations the good service range was only about half a mile from the aerial Now, although it has the same wave length as Hull, it has a good service range exceeding five miles The chief sphere of usefulness of this new method is to bring first class service to isolated towns Low powered stations and short wave lengths would be used, as all the regional high power stations need long wave lengths The method should appreciably relieve the broadcasting conditions in Europe

The Institute of Metals, founded for the study of Non Ferrous Metallurgy in 1908, which has just held its twenty first annual meeting, had an initial membership of about 250 To day the roll of its members exceeds 2000, of whom about two thirds are British and Empire members, while the remaining one third consists of foreign members At the time of its formation many doubts were expressed whether such an institute could be formed and maintained, and whether it would fulfil any really useful function When the successful career of the Iron and Steel Institute was cited as an encouraging example, the doubters pointed out that the non ferrous industries were much smaller, less wealthy, and less advanced

from a technical and scientific point of view It was even feared that manufacturers might not wish to support such an institute and that they would decline to allow the members of their staffs to take part in its meetings for fear of divulging confidential information Fortunately, the small band of enthusiastic founders of the Institute did not permit themselves to be deterred by such misgivings, and as soon as a start had been made it became abundantly clear that a real need existed for an institute dealing with the non ferrous metals From the very beginning the Institute prospered Its membership began to grow steadily and still continues to increase to day, while the value of its work and influence stands fully recognised both in Great Britain and abroad Its first three presidents were the late Sir William White, the late Sir Gerrard Muntz, and the late Prof W Gowland, representing respectively the user, the manufacturer, and the scientific student of metals This order of rotation in filling the presidential chair has been followed, with a few exceptions in special circumstances, throughout the past history of the Institute It is intended to emphasise the fact that the Institute seeks to serve the interests of all those directly concerned with the non ferrous metals, whether as users, manufacturers, or scientific investigators and teachers of metallurgy

A provisional notice of the forthcoming International Congress of Forestry Experimental Stations, to be held at Stockholm and elsewhere next July, has already appeared in Nature (Dec 1, 1928, p 852) The sessions of the Congress will take place in Stockholm during the week July 22-27, an excursion being paid during the week to visit forests at Noorköping and Katrineholm Although the deliberations of the Congress are confined to a week, the programme laid down is more comprehensive Two extensive tours, one in the south and the other in central and north central Sweden, are projected, each covering eight days, during which a considerable part of the country will be traversed Those members wishing to participate in the first tour will assemble at Malmö on July 14, arriving at Stockholm on July 20 During this period interesting forests will be visited at Dalby, Furen, Bokenäs, Malingsbo, Siljansfors, and in the region of Siljan and Domnarvet A number of private forests (pine, spruce, and beech) will be visited on this southern tour Also the pine and spruce State forests of Malingsbo in Dalarna, where the College of Forestry has instructional forests, and the experimental forests of Siljansfors, which are under the management of the Experimental Station and in which research work is undertaken This excursion will conclude with a trip through the beautiful country round Lake Siljan, when the rafting in the Daläven River will be seen and a visit paid to the town of Falun, an ancient ore mining and forest industries centre

The second excursion which has been arranged for the International Congress of Forestry Experimental Stations will prove of even higher interest Members will leave Stockholm for Bispgården on July 28 and will visit forests and forest industrial works at Kulbäcksliden, Svartberget, Lycksele, Hoting, Frösön to Åre, situated in the highlands of Jämtland, where amongst other things of interest the wonderful waterfall of Tännforsen will be viewed The intention of the northern tour is to demonstrate the forestry problems of Norrland and the difficulties incurred in slow growing northern forests with a more or less sterile soil Rafting and the industrial side of forest work in Sweden, which is of such great importance to the commercial well being of the country, will be seen The programme laid down for this Congress is extensive and can scarcely fail to be productive of work of importance to forestry science, whilst the members will have an opportunity of becoming acquainted with some valuable aspects of Swedish forestry methods

The following were elected fellows of the Royal Society of Edinburgh at a meeting held on Mar 4 Dr S G Barker, director of research, British Research Association for the Woollen and Worsted Industries, Leeds Dr F Bath, lecturer in mathematics, University of St Andrews, Mr G Bennet, lecturer in mechanical engineering, Heriot Watt College, Edinburgh, Dr A Calder, assistant in the Animal Breeding Research Department, University, Edinburgh, Dr G Coull, pharmaceutical chemist, of Leith, Prof E W H Cruickshank, Physiology Department, Dalhousie University, Halifax, Nova Scotia, Mr D Kennedy Fraser, psychologist to the Education Authority, Glasgow, Mr T Henderson, actuary of the Savings Bank of Glasgow, Dr Sunder Lal Hora, senior assistant superintendent, Zoological Survey of India, Calcutta, Prof J Kendall, Chemistry Department, University of Edinburgh, Mr J R Little, general manager and secretary of the Century Insurance Co, Edinburgh, Prof D N M'Arthur, Department of Agricultural Chemistry, West of Scotland Agricultural College, Glasgow, Mr J Mackie, mathematical master, Leith Academy, Leith, Mr W Mercer, lecturer in clinical surgery, University of Edinburgh, Mr H Moir, president, United States Life Insurance Co, in the City of New York, Prof F W Ogilvie, Department of Political Economy, University of Edinburgh, Dr J F V Phillips, botanist, Tanganyika Territory, Mr S Read, Edinburgh Academy, Mr R A Robb, lecturer in mathematics, University of Glasgow, Principal J C Smail, Heriot Watt College, Edinburgh, Prof Sydney Smith, Department of Forensic Medicine, University of Edinburgh, Dr T Southwell, lecturer in helminthology, School of Tropical Medicine, Liverpool, Mr A C Stephen, assistant, Natural History Department, Royal Scottish Museum, Edinburgh, Dr B P Wiesner, lecturer in sex physiology, University of Edinburgh

The United States Bureau of Mines has issued its report upon coal production in 1926 It consists, as usual, of numerous detailed statistical tables, whilst there is also much interesting information explaining the changes from year to year in the statistics quoted The greater part of the report is interesting only to coal workers in the United States, but there are some passages which coal producers, and especially coal miners in Great Britain, would do well to take to

heart Thus the report states that "The foreign demand was unusually intense because of the seven months' suspension of production in Great Britain The general walkout of the British miners on May 1 immediately started discussion of exports from this country" "A gain of approximately 14,000,000 net tons of shipment to Europe represented the greater part of the growth in the sea borne trade in 1926 This coal displaced former British tonnage in the main and went chiefly to the United Kingdom, Irish Free State, Italy, and France"

ENGINEERS engaged in designing will be interested to know that Messrs Adam Hilger, Ltd, are now making Prof Coker's well known apparatus for the study of the stresses in engineering structures by means of the double refraction which stresses produce in transparent models, and the effect this double refraction has on either plane or circularly polarised light passing through them Models of celluloid, stressed in their own planes, are used up to 3 inches long In circularly polarised light the areas of maximum stress are immediately apparent, and for many purposes this will be sufficient for the engineer If the actual magnitudes and directions of the principal stresses at each point are required, a more detailed examination under plane polarised light and with an auxiliary sheet of the same celluloid in simple tension used as a standard of stress is necessary

IT has well been said that the aspiration after the understanding of human nature and human actions is the key to much that is characteristic of the present century It is beginning to be realised that science is the new humanism, and that industrial aspects of it have to be considered not merely as profitable enterprises but also in relation to social welfare We therefore welcome the announcement of the publication of a new monthly magazine—*The Realist*—which will aim at presenting contacts of scientific discovery and other forms of creative expression with social, economic, and political affairs of the modern world The magazine has a strong editorial board representative of many fields of progressive thought and action, and it should make a wide appeal to intelligent citizens who seek something more substantial than they usually find in journals devoted to literary and political trivialities The first number is to appear on Mar 26, and will be issued by Messrs Macmillan and Co, Ltd, for the Realist Publishing Co, 25 Victoria Street, S W 1

THE Torquay Natural History Society shows satisfactory progress In spite of the fact that the building of an extension to the Museum interfered with the ordinary course of museum work, a varied programme of twenty two lectures was carried through The addition of a second storey to the museum has permitted the exhibition of a loan collection of ethnographical specimens and of much material formerly stored away The activities of the Society are carried on by a series of sections with specialised interests, the most lively being the archæological, the botanical, and the entomological In each of these, papers of general and local interest were read, and some of these have been published in the *Transactions*

THE Report of the Museums of the Brooklyn Institute of Arts and Sciences for 1927 gives a great impression of activity and progress, not only in the field of exhibition pure and simple, but also in many side activities aiming at the education of the student and the people in general The Department of Natural History has been given much additional room for expansion, many new galleries, three of which have been converted into European period rooms, have been opened, a large annex has been adapted for the Children's Museum at a cost of some £10,000, and a lunch and tea room has been created The energy of the staff is indicated by the fact that ten special exhibitions of various art collections and eight exhibitions of prints were held in the course of the year Special educational activities include the institution of a press for printing lithographs for the use of students, the formation of a class in clay modelling for children in the elementary schools, the exhibition of motion picture films portraying the "Chronicles of America," and zoological subjects (purchased from Raymond L Ditmars) for school children, as well as lecture courses for the public for teachers, and for students The Children's Museum with its loan exhibits of natural history specimens, its school visits helped by three teachers assigned by the education authorities, its summer field trips, and many other activities, ought to instil the scientific mood at a period when it is most likely to have a telling influence The cost of running these excellent museums during the year was roughly £43,000 for the Central Museum, and £4700 for the Children's Museum

THE G J Symons Memorial Lecture of the Royal Meteorological Society will be delivered on Mar 20 at 7 30 P M, by Mr R A Watson Watt who will take as his subject "Weather and Wireless"

DR L F HEWITT has been appointed bio chemist at the Metropolitan Asylums Board's antitoxin establishment, Belmont Laboratories, Sutton, Surrey Dr Hewitt is at present Gibbons Research Fellow at the London Hospital, and was formerly research chemist, Medical Research Council, Mount Vernon, Hampstead

A VIOLENT earthquake was recorded at Kew Observatory on Mar 7 The first tremors reached the observatory at 1 hr 46 min 36 sec G M T The distance of the epicentre is estimated at 5400 miles, and the bearing is 7° W of N, corresponding with a position near the Aleutian Islands, lat 50° N, long 168° W

AN additional evening meeting of the Royal Geographical Society will be held on Monday, Mar 25, at 8 30 P M, at the Polytechnic Theatre, Regent Street, when Sir Douglas Mawson will give an account of recent work on the fjords of New Zealand and will show the kinematograph film of his Antarctic Expedition of 1911–1914, not before shown in England in its final form

MAJOR H O D SEGRAVE established a new speed record on Mar 11 at Daytona Beach, Florida, with an average of 231 36226 miles an hour Major Segrave was driving his Irving Special racing car *Golden Arrow*,

and covered the mile course in each direction at just over 231 miles an hour The *Golden Arrow* has a 12 cylinder Napier Lion engine which develops 930 h p and is not supercharged, the body of the car consists of three stream line forms The previous highest speed, 207 55 miles an hour, was attained by Mr Ray Keech driving Mr J M White's Triplex car on April 22, 1928

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —An assistant veterinary inspector under the Surrey County Council—The Clerk of the County Council, County Hall, Kingston upon Thames (Mar 20) A lecturer in electrical engineering at the Rugby College of Technology and Arts—The Organiser of Further Education in Rugby, 61 Clifton Road, Rugby (Mar 20) A head of the Mathematics Department and organising assistant to the Principal of Leeds Technical College—The Director of Education, Education Department, Calverley Street, Leeds (Mar 23) An assistant lecturer in botany in the University of Bristol—The Secretary, The University, Bristol (Mar 25) A deputy curator of the Sunderland Public Libraries, Museum, and Art Gallery—The Chairman of the Libraries, Museum, and Art Gallery Committee, Town Hall, Sunderland (Mar 25) A lecturer in physics at the Chelsea Polytechnic—The Principal, Chelsea Polytechnic, Manresa Road, S W 3 (Mar 28) A demonstrator for laboratory work in physics and electrical engineering at the Royal Naval Engineering College, Keyham (Plymouth)—The Secretary of the Admiralty (C E Branch), Whitehall, S W 1 (Mar 31) A head of the pharmacy department of the Leicester College of Technology—The Registrar, College of Technology, Leicester (April 3) A lecturer in the Department of Mining of the Imperial College of Science and Technology—Prof S J Truscott, Imperial College of Science and Technology—Royal School of Mines, South Kensington, S W 7 (April 15) A professor of biochemistry in the University of Alberta—The Secretary of the Board of Governors, University of Alberta, Edmonton, Alberta, Canada (May 14) A junior chemical assistant to the Research Association of British Flour Millers—The Director of Research of the Association, Old London Road, St Albans A senior science mistress at the County School for Girls, Beckenham—The Head Mistress, County School for Girls, Beckenham A bacteriologist in the Malayan Medical Service—The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, S W 1

Our Astronomical Column

TWO NAKED EYE SUNSPOTS —Two groups of sun spots, large enough to be seen with the naked eye, have recently been on the sun's disc at the same time The larger of these was a stream, with a big composite leader spot, crossing the central meridian on Mar 11 It was the return or revival of a group in the previous rotation with central meridian passage on Feb 12

The second group consisted of a single spot, fairly regular in outline, and showing bright projections partly across the umbra, there were small companion spots and a subsidiary stream southwards The following table gives other details of the two groups

No	Date on Disc	Central Meridian Passage	Latitude	Area
3	Mar 2–14	Mar 8 3	7° S	1/2000
4	Mar 5–17	Mar 11 0	10° S	1/800

(Areas express proportion of hemisphere covered)

CHANGES IN THE EARTH'S ROTATION —A paper by the Astronomer Royal and Mr R T Cullen was read at the meeting of the Royal Astronomical Society on Mar 8, in which the residuals in longitude of the sun for the last 150 years were compared with those for the moon It was found that a much greater accordance was produced by deducing the sun's longitude from the observed Declinations in the neighbourhood of each equinox, than by deducing it from the Right Ascensions The early observations of Right Ascension of the sun are affected by abnormal errors which do not enter into the Declinations to the same extent

The new reduction leads to a much closer resemblance between the curves of solar and lunar residuals than has previously been obtained, and thus strengthens the hypothesis that the cause of these fluctuations lies in the earth's rotation, not in the bodies themselves

MEASUREMENT OF STELLAR RADIATION —The recent considerable advances made by Pettit and Nicholson in the knowledge of stellar radiation has been made possible largely through the great 100 inch Hooker telescope, combined with the extremely delicate thermocouples and refined methods of measurement introduced by these two pioneers Their latest results are given in the *Astrophysical Journal*, vol 68, p 279, which includes an interesting account of the construction of the thermocouple This delicate operation, in which wires of about 0 03 mm are used, has to be performed under a microscope, and the resulting thermocouples are capable of measuring radiometric magnitudes with an uncertainty of only 0 1 of a magnitude A discussion of the observing methods used and the reduction of the observations is followed by the results obtained for the 124 stars so far observed Those are reduced to a homogeneous system of radiometric magnitudes, heat indices, and water cell absorptions, corresponding to the standard conditions of (1) the star in zenith, (2) two reflections from fresh silver, and (3) a rock salt window in thermocouple The corrections required to reduce to no atmosphere and for the total radiation reaching our system are given, as well as the computed bolometric magnitudes

DETONATING FIREBALL IN NEW ZEALAND —There has been evidence of a widely awakened interest in astronomy of late years in New Zealand One of the directions of its manifestation is the careful observation and discussion of meteors Mr R A McIntosh describes in *B A A J* for February a brilliant fireball that appeared over the Coromandel Peninsula (North Island) on the night of Oct 27, 1928 As the moon was full, and yet the object was so conspicuous, the magnitude is estimated as − 15, the explosion was seen by three observers, the meteor separated into three or four portions, which quickly died out The height at commencement was 75 miles, at the end 25 miles, the visible track being 107 miles long and the velocity 27 miles per second The explosion shook the houses, and was heard over a large area A faint trail was seen for 2½ seconds The radiant was at 6° + 24°, near Alpha Andromedæ

Research Items

CLIMATE AND HEALTH —The statistical relations between climatic factors and human health has been investigated by Dr A Wallen in a publication of the *Statens Meteorologisk Hydrografiska Anstalt*, Bd 5, No 1 of Stockholm, entitled "Vädevlekens Samband med Hälsotillståndet" Dr Wallen has studied the correlations between the mortality and health of Stockholm and Göteborg on one hand, and pressure, temperature, humidity, precipitation, and diurnal variation on the other No particular relationship is found between pressure and health, but mortality increases during high pressure both in summer and winter This, however, may be due rather to the associated high temperature in summer and low temperature in winter A close relation appears to occur between temperature and health Humidity also plays an important rôle Dry seasons at all times of the year show an increase in the mortality rate, and winters and springs with a high humidity are also marked by a high mortality No relation was traceable between the amount of precipitation and health or mortality Considerable diurnal variations in temperature or in pressure show correlations with an increase in the mortality rate Dr Wallen also traces correlations between meteorological factors and the number of workmen on sick leave in a large factory with 1000 employees A close correlation was shown in an increased number of cases during low barometric pressure The paper contains a large number of graphs and statistical tables, and a useful bibliography of the subject

HANDWRITING —*Science Progress* for January has an article on experimental graphology by R Saudek Handwriting being a very personal activity, one would expect on *a priori* grounds that it would be possible to deduce from it something of the personality of the writer Numerous attempts have certainly been made and while some people would seem to have had some success in individual cases, yet the scientific treatment of the subject is very recent From the legal point of view the aim of the graphologist is to discover whether the questioned document is the work of the reputed writer, and, if it is not, to prove the identity of the handwriting in its inconspicuous characters with that of the suspected person The assumption on which the expert relies is that the inconspicuous features of the handwriting cannot be consistently disguised in a manuscript of any length The problem of the diagnosis of the character of the writer is more complicated The writer of this article has subjected handwriting to a detailed analysis, and asserts that there are at least twelve factors that co operate in the formation of the individual writing These factors include the writing instruments, the degree of maturity of the writer, the acute physiological condition of the writer, and the speed of the act of writing etc Detailed explanations are given and specimens of handwriting illustrating the various points The kinematograph has proved useful in distinguishing some of the laws The research is interesting as marking a beginning of the study of this subject, though one is left with the feeling that much yet remains to be done

WILD BIRDS AND DISEASE IN THE POULTRY YARD — Various investigators have shown that a number of species of wild birds occasionally harbour a gape worm identical with that which causes severe epidemics amongst poultry (*Syngamus trachea*) Odd records refer to the pheasant, thrush, magpie, jay, and jackdaw A more serious infestation may occur in the starling, in which Lewis found that, in the Aberystwyth district, 169 out of 482 (35 per cent) carried the parasite Charles Elton and Frank Buckland have now discovered that a much higher percentage of the rooks in the Oxford district are similarly affected (*Parasitology*, vol 20, December 1928) The samples are small, but the results are striking of eight adults examined, four contained gape worms, and 31 out of 33 young rooks Rooks and starlings are frequent visitors to the poultry yard, and the possibility that they may be responsible for the distribution of gape worms amongst domestic fowls deserves immediate investigation The very high incidence of the presence of gape worms amongst young rooks may account in part for the mortality which they are known to suffer in the nest, and this also may be a factor of some economic importance

PARASITIC WORMS OF THE WILLOW GROUSE —A paper by Johan Huus (*Bergens Mus Aarbog*, 1928) forms one of the contributions to the extensive investigation recently completed on the biology of the willow grouse in Norway The alimentary tracts of 517 birds were examined and four species of worms obtained, namely, two nematodes—*Ascaridia compar*, *Capillaria longicollis*, and two cestodes—*Raillietina urogalli* and *Weinlandia microps* *Ascaridia compar* was found in the jejunum of 190 of the birds examined A careful account is given of the morphology, the distribution and the biology of the worm The larvæ of *Ascaris lumbricoides* and of *Ascaridia galli* are known to pass from the intestine into the blood stream and via the heart to the lungs, where they escape into the alveoli, and thence come into the trachea and pharynx, from which they pass into the stomach and intestine The author believes that the larvæ of *Ascaridia compar* have a similar course, for the youngest examples found in the duodenum were 3 mm long and were undergoing their last ecdysis There is no evidence that this worm is pathogenic, the passage of the larvæ through the lungs, especially in young chicks, may be harmful *Capillaria longicollis* was found only in three birds, in the duodenum *Raillietina urogalli* was present in the jejunum of 57 of the birds examined, and *Weinlandia microps* in the duodenum in 60 cases The author points out that parasitic worms were not present in the cæcum of the birds examined

RESEARCHES ON COPEPODS —Mr A G Lowndes, of Marlborough College, in continuation of his researches on freshwater copepods, has published two interesting papers, "Freshwater Copepoda from the New Hebrides" (*Annals and Magazine of Natural History*, Ser 10, vol 1, June 1928) and "The Result of Breeding Experiments and other Observations on *Cyclops vernalis* Fischer and *Cyclops robustus* G O Sars" (*Internat Revue der ges Hydrobiol u Hydrographie*, Bd 21, Heft 3/4, 1928) The first of these deals with a collection of copepods made by Dr J R Baker from a large lake on the Island of Gaua The lake is more than 300 feet deep, the pH at the surface and middle layers was 8 5 and the temperature 25° C Five species of copepods only were obtained, all but one well known and of wide distribution It is very interesting to find that in the majority of cases little or no difference in structure is visible between the forms from the New Hebrides and those from the British Isles and elsewhere No Calanoids were found in this collection In a sample from Hog Harbour, Santo, *Cryptocyclops anninæ* occurred in abundance in empty coco nut shells In the second paper Mr Lowndes describes the result of breeding together the two copepods *Cyclops vernalis* and *Cyclops robustus*, the object of the work being to decide whether *C robustus*

should be regarded as a separate species or only as a variety of *C vernalis* The specific characters are based almost entirely on the spine formulæ and on the nature of the setæ Mr Lowndes has shown in previous breeding experiments on *Cyclops* that the spine formulæ may be exceedingly variable and too much importance must not be attached to these for the identification of species The experiments were carefully carried out, and in addition cultures were made from the adult female of *C robustus* which gave rise to *C vernalis* *C vernalis* was successfully crossed with *C robustus* Both forms occur together in the same pond with every gradation between the two It is concluded from these observations that *Cyclops robustus* is not a separate species, but only a form of *Cyclops vernalis*

FISHES FROM FLORIDA AND THE WEST INDIES — In the paper under this title (*Proceedings of the Academy of Natural Science of Philadelphia*, vol 80, 1928), Mr Henry W Fowler reports on collections obtained in Florida, the Bahamas, Haiti, Porto Rico, Saint Lucia, and Dominica The specimens, except the Porto Rican collection are in the Academy of Natural Science of Philadelphia Several hundred species are recorded, but none is new, although there are new localities for many of the fishes and some are specially interesting in their distribution The author also mentions nineteen examples of *Rivulus hartii* (Boulenger) from Pitch Lake, in Trinidad, British West Indies which were presented to the Academy by Dr Judson Daland in April 1928 Some of the species from Florida are new to the United States fauna These include a specimen of *Rivulus cylindraceus* Poey which is re described There are some rare fishes from the Bahamas One specimen of *Sparisome radians*, 81 mm long, was taken from the stomach of *Serranus striatus* From Bermuda three examples of *Halichœres radiatus* are recorded and one of *Callyodon plumbeus* A collection of 69 species come from Haiti obtained by Mrs James Bond in the Porto Prince market Valuable colour notes are given for many of the fishes

THE BLOOD OF INVERTEBRATES —The holothurian *Caudina* is a favourite subject for physiological research and is specially interesting, for not only is there hæmoglobin in its blood, but also this is contained in corpuscles, as Hogben recently described in a South African *Cucumaria* Two papers in the *Science Reports of the Tôhoku Imperial University* (4th series (Biology), Sendai, Japan, vol 3, No 4, Fasc 1, 1928) deal with the subject In "Chemical Studies on Sex Differences of Blood Protein in *Caudina chilensis* J Muller," Tetsutaro Tadokora and Shukichi Watonabe have followed up their researches on sex differences in the blood protein of mammals They contend that similar differences are found in *Caudina* Mr Nobukuki Kawamoto ("Oxygen Capacity of the Blood of Certain Invertebrates which contain Hæmoglobin") uses the mollusc *Andara inflata* as well as *Caudina* for his experiments Both contain hæmoglobin in the blood corpuscles, and the present work was undertaken in order to make a comparison with the blood of invertebrates having no hæmoglobin, such as those used recently by other workers (*Helix*, *Octopus*, *Homarus*, *Astacus*, *Cancer*) It is shown that compared with the higher Mammalia, the blood of *Andara* and *Caudina* absorb much less oxygen, but compared with the invertebrates quoted, the oxygen capacity is much greater It is also greater that that of sea water

EARLY HISTORY OF COTTON —A N Gulati and A J Turner, of the Technological Laboratory of the Indian Central Cotton Committee, have an interesting note on the early history of cotton in *Bulletin* No 17, Technological Series No 12, issued in October 1928 by this Committee (The same paper appears in the *Journal of the Textile Institute*, 20, pp T1 19, January 1929) The earliest known mummy cloths in Egypt, according to Petrie date from about 5500 B C and are made of flax No Egyptian mummy cloths appear to have been made of cotton, but mummy cloths of cotton have been found in Peru, where one species of *Gossypium* seems to be indigenous Recently, scraps of cotton material have been found amongst the remains of the prehistoric civilisation unearthed at Mohenjo daro in Sind These remains belong to the three latest cities erected on this site, which are ascribed to dates between 3500 B C and 2400 B C Messrs Gulati and Turner have made as full an examination of this material as the condition of its preservation permits, and conclude that the cotton is not of the *G herbaceum* type, but more closely related to the coarser fibres of the *G arboreum* type One sample of string found in earthenware had a purple colour, a few tests made on this sample suggested that the dyestuff originally employed was of the madder type

ABACÁ A LITTLE KNOWN PHILIPPINE FIBRE The Cordage Institute of the United States has made possible a detailed study of the conditions of cultivation and production of 'abacá' fibre This product is obtained from the outer, lower side of the long fleshy leaf stalks of *Musa textilis* Née which overlap to form the main stem of this plant The industry is indigenous to the Philippines, where the fibre has been known since Pigafettas' diary of Magellan's trip around the world (1519), in which the name first appears A million or more bales of fibre from cultivated varieties of this plant are annually exported from the Philippines whilst fibre is now also being produced from the same plant in Borneo, Java, and Sumatra During recent years a scientific study of the crop and its product has been initiated, and the *Philippine Journal of Science*, Vol 37, No 1, Sept 1928, contains a series of papers by P L Sherman, Cordage Institute Fellow, and his colleagues of the Bureau of Science, Manila, which give the first results of this work These papers deal largely with the soil conditions and the state of the fibre as originally prepared Active fermentation processes are at work in the soil owing to the mass of rotted vegetable material from the leaf debris left after cutting out the fibres partly as a result the extracted fibre is usually somewhat full of acid materials, and the writers point out that unless it is thoroughly dried before it leaves the collecting ground, there is great danger of rapid deterioration in storage

FOSSIL OSTRACODA OF ITALY —A monograph on the fossil Ostracoda of Italy has been begun by A Neviani The first part (*Mem Pont Accad Sci N Lincei*, Ser 2, vol 2) treats of those from the classical beds of Vallebiaja, near Faugha, which the author refers to the Lower Calabrian of Gignoux Nearly 70 species are described, about 18 being considered new, and the details of their occurrences in time from the Mesozoic to the present day are set forth in tabular form There is a good index and two excellent plates

THE BUSHVELD COMPLEX OF THE TRANSVAAL — Among the spectacular geological phenomena for which South Africa is becoming increasingly famous, the great body of igneous rocks known as the Bushveld complex occupies an impressive position Molengraaf, Mellor, Hall, Wagner, du Toit, and other pioneers have already established its principal

features, and now a valuable summary appears from the able pen of Prof R A Daly, accompanied by eighteen new analyses and a stimulating discussion of the kind which enlivens all his contributions to geological literature (*Bull Geol Soc America*, vol 39, pp 703 768 , 1928) This paper should be of special value to geologists attending the South Africa meet ing of the British Association and the meeting of the International Geological Congress Some of Daly's conclusions differ from the current interpretation of the Union Geological Survey According to the latter, the Bushveld felsite is excluded from the complex and assigned to a Rooiberg series which is made the top of the Transvaal system Daly thinks that the felsite is at least partly, and possibly wholly, a definite member of the complex, akin to the roof of the Duluth 'lopolith' which seems to have been in part its own extrusive phase, chilled against the atmosphere It is also suggested that the coarse granites of the Complex are not contemporaneous throughout, but are made up of two main intrusions, one red, pre ceding the norite, and the other pink and slightly more mafic, succeeding the norite It is recognised that the Complex will long furnish genetic problems of fundamental importance to geologists and petro logists In this paper the difficult questions of magmatic origins are touched on but lightly

LAPLAND METEOROLOGY — The observatory at Abisko, on Lake Torne in Swedish Lapland, has pub lished its detailed observations for both 1926 and 1927 The headings to the tables are in Swedish and French The usual meteorological data are given in full In addition, there are a number of valuable records on the hydrology of the lake, including its weekly tem perature at a depth of one metre, the dates of freezing and breaking up, and the thickness of the ice at weekly intervals during the long period from November to June, when the lake is frozen Soil temperatures, on every fifth day throughout the year, are given for depths of 50, 100, 150, and 200 cm There are also full notes on the displays of aurora borealis These publications are valuable contributions to the study of Arctic Europe

AUTOMATIC LEVEL GAUGE ALARM —The application of photoelectric and selenium cells to operate alarms and automatic controls regulating the level of liquid in tanks and stand pipes is an interesting example of the growing industrial application of these instruments The device is especially useful when the liquids are under high pressures, as then the standard methods of level control are inapplicable The following simple arrangement is in use at the works at Billingham of the Synthetic Ammonia and Nitrates Limited A glass in spection gauge is fitted at the required level on the stand pipe and the light sensitive relay is illuminated through the gauge Using opaque liquids, the light is shut off when the liquid rises and the relay then operates an alarm signal When transparent liquids are used, an opaque float in the gauge glass can be used to shut off the illumination when the liquid rises Alternatively, the light sensitive relay and the light source may be mounted on the same side of the gauge glass and the relay illuminated by a beam reflected by total internal reflection at the inner surface of the glass In this case reflection ceases when the liquid rises, the beam of light being refracted through the liquid The latter method is convenient when flat gauge glass, to which a right angle prism can be cemented, is used

PHOTOSYNTHESIS OF CARBOHYDRATES — Prof E C C Baly's production of carbohydrates by the exposure to light of carbonic acid which had been deposited on the surface of nickel or cobalt carbonate, of which an account was given in the *Proceedings of the Royal Society* for 1927, has now been shown by him and N R Hood to show an additional resemblance to natural processes in its susceptibility to the influence of temperature (*ibid*, A, vol 122, p 393, Feb 4) The yield of carbohydrates in his experiments increases linearly with temperature to a maximum at 31°, photosynthesis by some algæ has been long known to obey a similar law, and it is now found that the tem perature coefficients for the changes are almost the same in the two cases Above 31°, the yield again decreases in his experiments, and becomes almost zero at about 48°, a botanical analogue of this is known in the existence of an optimum temperature for natural photosynthesis by leaves, with an assimilation-temperature curve which is very similar to that found by Prof Baly, showing in particular a sharp peak at 37° Prof Baly has not discussed in any detail exactly what occurs in the purely physico chemical processes with which he had been concerned, but it is evident from the similarities that he has pointed out that many of the characteristics of the natural phenomena are merely those of a pure photochemical surface re action

TRANSMUTATION OF ELEMENTS —In an X ray tube there is a large localised dissipation of energy in the neighbourhood of the focus spot, where the electrons are incident on the anode If it were possible to bring about transmutation by moderate quantities of energy, conditions here would appear to be particu larly favourable, and any positive results obtained would carry considerable weight, since the substance being studied remains in a high vacuum throughout the experiment, and is thus not liable to chance contamination At the suggestion of Prof R A Millikan, tests of this nature have been made by L Thomassen in the Norman Bridge Laboratory at Pasadena His results, which are described in the February issue of the *Physical Review*, are completely negative no change was found in the characteristic X ray spectrum of a tungsten target before and after the tube holding it had been operated for three days at a peak potential of 207 kilovolts and a current of a few milliamperes The same author has also re peated the experiments of Prof Smits, from which it appeared at one time that lead might be transmuted into mercury, and has obtained no evidence of change in a lead arc, and inconclusive results with a high potential discharge between lead electrodes immersed in carbon disulphide, his conclusions in the latter case being similar to those afterwards arrived at by Prof Smits himself (see NATURE, Jan 2, 1926, p 13, and Oct 1, 1927, p 475)

PHOTOCHEMICAL DECOMPOSITION OF NITROGEN PENTOXIDE —The decomposition of nitrogen pent-oxide in the presence of the dioxide, which photo-sensitises the reaction, using monochromatic radiation of wave lengths 4350, 4050, and 3660 A, has been investigated by Baxter and Dickinson Their results, which are described in the *Journal of the American Chemical Society* for January, appear to follow the mechanism suggested by Norrish The first reaction is probably a decomposition of the dioxide into nitric oxide and oxygen This is followed by a dark re-action between nitric oxide and nitrogen pentoxide $NO + N_2O_5 = 3NO_2$ In the decomposition of nitrogen dioxide the quantum efficiency for radiation of wave length 4350 A is extremely low (0 0046 molecules of oxygen produced per quantum absorbed), and hence this wave length should be ineffective for the decom-position of the pentoxide This was actually found to be the case, since the effect with radiation 4350 A was too small to be detected with the apparatus used

The Eucalypts and Paper Pulp

THE paper pulp problem, especially with reference to what is termed newsprint or the material used by the daily press, is one of growing importance in many countries to those concerned At first sight it would not, however, have been considered by the average man in Great Britain that the question had become one of importance in Australia, yet it appears that, with an annual consumption of 120,000 tons of newsprint, Australia comes next to the United States of America and Canada on the basis of requirements per head of population. None of this paper is made in Australia, the reason given being that "existing processes of manufacture require light coloured coniferous wood that can be readily converted into pulp by purely mechanical means" This ground wood or mechanical pulp comprises 70 to 80 per cent of the fibre content of newsprint, the remainder being pulp from the same wood chemically prepared by the sulphite process and added to impart the necessary strength to the sheet

This being the position, the problem which has to be solved before newsprint can be manufactured in Australia is the discovery of a substitute for mechanical pulp that will compare with it favourably in the quality of the paper, as also in price The problem is no new one In India, investigations in connexion with various bamboos and grasses have been carried out at the Forest Research Institute for nearly a score of years past So far as quality goes, previous investigations in Australia (*Bulletin* No 25, Council for Scientific and Industrial Research Melbourne H J Green) have shown that it was possible to produce from the eucalypts bleached soda pulp much superior in quality to ground wood, and the indications were that on a large scale this pulp could be made at a cost not very much above the latter Experimental work in this matter had been carried out in connexion with the mountain ash (*E regnans*), Victoria, stringy bark (*E obliqua*), Tasmania gumtop (*E delegatensis*), Tasmania, beech (*Fagus Cunninghamii*), Tasmania, and *Pinus insignis* This work was, however, considered to be too incomplete to be worth publishing In connexion with *P insignis* it has been shown that it makes excellent sulphite pulp, as well grown *P insignis*, of 15 20 years of age, carry only about the same amount of resin as spruce

More detailed researches have since been undertaken by Messrs L R Benjamin and J L Somerville ("Paper Pulp and Cellulose from the Eucalypts by the Sulphite Process" *Bulletin* No 37, 1928) This bulletin deals with the research work carried out during the last four years on the problem of applying the sulphite process to the pulping of eucalypts from the practical viewpoint and bearing in mind the limitations imposed by existing industrial equipment The authors, in discussing their objective, remark

"The precedence in point of time accorded the soda pulping investigations was based entirely upon the fact that the so called 'hardwoods' are seldom pulped by any other than alkaline processes In this connexion it may be added that, by whichever process hardwood is pulped in other countries the product is almost invariably soft, bulky, and of low strength, its use being confined almost entirely to the manufacture of book papers in which the relatively high proportion of longer fibred sulphite pulp from soft wood is relied upon to impart the desired strength In other words, hardwood pulp is used abroad as a filler for imparting softness and opacity In *Bulletin* No 25, previously referred to, it was shown, however, that pulp of good colour and high strength could be obtained from the eucalypts by a suitable modification of the soda process, followed by proper bleaching and heating The experience thus gained has been of considerable value in the planning and conduct of the present investigation, one of the principal objects of which has been to find those cooking conditions that would give pulp possessing good strength and a colour sufficiently white, without bleaching, to be used, either alone or in high proportion, in the manufacture of newsprint Other aspects have also been considered, such as the production of high grade cellulose for use in the manufacture of artificial silk, but work in this direction has been restricted and mostly controlled by the necessity or desirability of acquiring evidence in support of certain trends, or of collecting incidental information that might be of value in establishing the proposed Australian newsprint industry"

The chemistry of the sulphite process, even at the present time, is incompletely understood, and there are many points connected with its application to the pulping of the eucalypts which the authors consider would well repay thorough investigation if the industry already existed in Australia, but they thought that for the present they should concentrate their investigations upon developing methods that would permit of ready application and be sufficiently economical to aid materially in the early establishment of the sulphite industry and the production of newsprint

Those interested in this matter should consult this very interesting and valuable monograph The authors' objects and results are expressed in the following

"Preliminary investigations with the sulphite process pointed to the possibility of cheapening production to the required degree, and subsequent systematic study of the process has practically assured this, for it is now evident that bleaching can be eliminated and a pulp produced so much superior in quality to mechanical pulp that the admixture of longer fibre for conversion into newsprint will probably not be necessary Hence, as far as the production of a suitable substitute for mechanical pulp is concerned, the results of the present investigation indicate that this is entirely feasible

"Apart from the demand for newsprint in this country, there is a large consumption of the better grade printing papers and writing papers in which high grade sulphite pulp is used In addition to this there is a very heavy and increasing demand for artificial silk both in yarn and in the form of piece goods These facts should stimulate the production of high grade bleached cellulose once a newsprint industry relying on sulphite pulp is established Accordingly, when it was found that the cooking conditions required for producing pulp sufficiently white in the unbleached state to be used in newsprint also closely approached those necessary for the production of high grade cellulose, the opportunity was taken of exploring the possibilities further As a result, considerable information on the physical qualities of the pulp, and the chemical purity of the cellulose produced in this investigation has been collected, and is now placed on record"

If this research work and experiments are translated into commercial operations, they should have an important outcome in the management of certain of the Australian forest areas Their study will also repay countries in which the Eucalyptus has been successfully grown in plantations

Natural History in Norfolk.

PROVINCIAL natural history societies may, and in many cases certainly do, perform very useful functions in keeping alive an active interest in Nature and the preservation of the local fauna and flora, but actual original work is generally confined to a small minority of members Indeed, it is one of the chief difficulties in keeping such societies alive that the active members bear so small a proportion to the whole A further difficulty exists when such societies also publish *Transactions* On one hand, such a publication must, if it is to justify itself, maintain a certain standard of interest and originality, on the other it is not advisable that it should be the medium of publication of original work of wide general interest, since the limited circulation of the journal makes it difficult of access, at all events in other countries The papers published should deal primarily with the natural history, in its widest sense, of the locality, so the series of volumes should form a mine of trustworthy local information

The Norfolk and Norwich Naturalists' Society has published its *Transactions* yearly, without a break, from its foundation in 1869, and has probably come as near as is possible to maintaining a general interest and value in its publications without going beyond its proper limitations The part just published (vol 12, part 4) opens with an account of the Mycetozoa by the president, Mr H J Howard, illustrated by some remarkably fine photomicrographs, and including a complete list of the Norfolk species Of the total of 121 species, Mr Howard has added sixty to the county list, and among these one new to Britain and two varietal forms new to science The paper should be of much value to anyone working at this group, by reason of the information given as to the nature of the habitat and season of appearance A paper on the Swan Marks of East Norfolk, illustrated by figures of 160 of these marks, by Mr Norman F Ticehurst, embodies the results of an enormous amount of patient research and is of much more than purely local interest

Prof F W Oliver writes with his usual charm of a visit to Holland for the purpose of seeing the progress of experiments in reclamation by means of *Spartina Townsendi* He has dealt with the subject in greater detail in other publications, but Norfolk has so much in common with Holland that what he has to say on this subject, and about the Nature reserves and flower culture in Holland, is of special interest to East Anglians

A paper on the survey of Scolt Head Island by Mr O D Kendall and Mr J A Steers is a continuation of work intended to record the progressive changes in sand dunes and shingle banks due to tide and wind, two maps and a section illustrate the results of the survey

Norfolk is fortunate in having the two National Trust properties of Blakeney Point and Scolt Head Island, both of which are being studied so effectively Blakeney Point has already become famous from the work done by Prof Oliver and his pupils, and at Scolt Head work on similar lines, under the supervision of Mr Steers, is producing results of wide and permanent interest The annual report of the Wild Birds Protection Fund again shows what excellent work in preservation of the local animal life can be done by provincial societies under the stimulus of an energetic personality The Norfolk Wild Birds Protection Committee owes its existence to Dr Long, and it is to him also that Norfolk owes the formation of the Norfolk Naturalists Trust, which owns a large area of marshes at Cley and intends to acquire other properties when the existence of rare birds seems likely *to be threatened* The report includes some remarkable records of ducks shot at Hickling and Ranworth, those for the latter going back to 1920 From these figures it seems that the numbers of wild fowl are not, as has been supposed by some, on the decline

The *Transactions* include also an article by Mr Stuart Baker on the scientific results to be obtained by egg collecting, and a paper by Mr Carruthers on planting at Scolt Head The latter is of general interest since much may be learnt from it as to the precautions to be taken in planting in such an exposed situation and on dunes

The Storage of Food

THE Report of the Food Investigation Board for 1927 [1] covers a wide range of problems connected with the subject of the storage of food, from purely scientific investigations to large scale experiments on food transport and the necessary engineering practice A considerable amount of work has been carried out on the transport and storage of fruit, especially apples, and on the changes taking place during storage which lead ultimately to its decay Ships' holds are not air tight, leaks occurring through hatches or wooden bulk heads between holds, from the low percentage of carbon dioxide frequently found, it appears that at least one third of the air present may be changed daily Well riveted steel bulkheads, however, allow of little leakage The question is of importance, both from the point of view of maintenance of a particular temperature in the hold, and also because the storage life of fruit depends in part on the composition of the surrounding air The conduction of heat from the ship into insulated holds along frames and beams projecting into the insulation, and the heat generated by the fruit itself in storage, have also to be taken into account in the design of refrigerators At 20° C sound apples generate heat at the rate of about 0 012 cal per sec per kgm, or 0 0015 cal per sec for an individual apple, in other words, an apple in 23 hours would raise the temperature of an equal weight of water 1° C if there were no heat loss In practice the temperature in the centre of the store is taken by means of a distance reading thermometer, of which a number of types have been studied

Numerous investigations have been carried out on the changes taking place in apples during storage and the factors influencing them It has been found that the smallest fruit have the lowest respiratory activity, and that the maximal rise in this activity is smaller and later than in larger apples at the same time, the smaller apples usually have the longest life A low respiratory activity therefore delays the onset of internal breakdown in storage The nature of the soil on which the fruit is grown has a definite effect on storage life apples off a heavy soil keep twice as long at 34° F as those off a light soil, whilst the keeping quality is also correlated with the 'available' potash and phosphoric acid in the soil The nitrogen content of different kinds of apples tends to remain fairly constant, a higher nitrogen content is associated with a

[1] Department of Scientific and Industrial Research Report of the Food Investigation Board for the year 1927 (London H M Stationery Office, 1928.) 4s net.

higher respiratory activity The amount of sucrose and acid present, however, varies considerably from one type to another, and is also affected by the nature of the season thus cold weather raises the acid content, at the same time decreasing the sucrose value, warm weather having the reverse effect By such changes season can alter the keeping qualities of the fruit, since life depends on the presence of respirable material During storage the sugar and acid disappear at a constant rate and breakdown occurs when the store of respirable material is exhausted Gas storage also delays breakdown by slowing the respiratory processes, but just before death there is a sudden increase in the utilisation of sugar

It has been found that the optimum temperature for gas storage is higher than that used for cold storage by gas storage is meant an increase in the carbon dioxide concentration above 5 per cent, with a corresponding decrease in the oxygen percentage Gas storage at a low temperature in fact accelerates internal breakdown, but at a temperature above about 40° F gas storage gives better results than cold storage alone In addition to the internal breakdown which occurs at low temperatures, appearing, however, only after six to ten weeks storage, there is another type of breakdown which is hastened by higher temperatures and occurs especially in imported apples it can be avoided by gathering the fruit before a certain critical stage of maturity on the tree has been reached and its onset is definitely delayed by cold storage

In addition to breakdown, fruit in store may be attacked by fungal disease the resistance of the fruit depends on a variety of factors, such as acidity water, nitrogen, and potassium content, and hence on the locality in which the fruit is grown A low water and nitrogen content and a high acidity and potash content are associated with a high resistance, the converse is also true

Another problem which has been investigated is the best method of bringing cold stored produce back to a normal temperature a rapid rise in air temperature leads to wetting of the fruit from condensation of water on its surface, since its temperature only rises slowly Two methods of preventing wetting are available a slow and uniform rise in temperature or drying of the air during warming which may be the better depends on knowledge of the rate of evaporation from the fruit to be warmed, a problem which requires further investigation under practical conditions

Further work has also been carried out during the year on meat and fish and their products The conditioning of beef hung at a temperature of 41° F has been studied there is a progressive increase in tenderness especially noticeable in the coarser joints or in inferior quality carcasses, and even after 17 days the meat is still perfectly sweet

It is now well known that, to obtain meat fit for consumption freezing should be rapid to avoid the formation of large ice crystals when the crystals are only small, on thawing the meat closely resembles fresh meat It has now been found that bacon can similarly be frozen and be edible on thawing again, but the temperature necessary is considerably lower than that required for meat or pork For pork, - 10° C may be sufficient, but for mild cured bacon, - 15° C at least is necessary for rapid freezing, the freezing point of the bacon being several degrees below that of pork The practicability of freezing bacon at - 15° C and then storing it at - 10° C is now being examined

Investigations of fish by products have included the nutritive value of fish meals and the use of fish skins as a substitute for isinglass It was found that seabream meal in the diet of pigs resulted in better growth than was given by the best white fish meal or blood meal and sterilised bone flour moreover, the growth was made at a smaller expense in food than in the case of ordinary fish meal, a fact of considerable commercial importance Similar results were obtained with rats, and the seabream meal also produced better calcification of the bones than white fish meal The seabream is an oily fish which is not much used for human consumption Work has also been carried out on the nature of the sterols in marine animals and on the constitution of squalene and certain of the higher alcohols, problems which may be found to have a bearing on the storage or use of the various products for human consumption

University and Educational Intelligence

CAMBRIDGE —The Council of the Senate has presented a report to the University on an offer by the Medical Research Council to equip a Nutritional Laboratory on a site at the Field Laboratories, and has recommended that the offer be gratefully accepted

LONDON —The University College Committee will award in June next a Bayliss Starling Memorial Scholarship of the value of about £120 (with exemption from tuition fees) Candidates may be graduates or undergraduates of approved standing in science or in medicine The Scholar will be required to follow a course of study approved by the Jodrell professor of physiology involving a training in the principles and methods of research in physiology and/or biochemistry Applications must be submitted on or before May 15, to the Secretary of University College, London (Gower Street, W C 1)

A movement has been for some time in progress to endow the chair of engineering at University College in order to commemorate the great and enduring influence of the late Sir Alexander Kennedy on engineering education This appeal has met with a wide response nearly £19,000 has been raised of the £30,000 required In a letter supporting the appeal, the presidents of the Royal Society and of the Institutions of Civil, Mechanical, and Electrical Engineers direct attention to Kennedy s pioneer work and the need of a permanent memorial Subscriptions may be sent to Lord Meston the Treasurer of this Fund, at University College

MANCHESTER —The University has received a bequest of £300 under the will of the late Miss Amy Henrietta Worswick In accordance with the wishes of the testatrix, the bequest will be devoted to the investigation of the causes and treatment of rheumatoid arthritis A temporary fellowship of the value of £150 per annum will be offered, and application may be made to the Registrar before Oct 15 next by any person who has obtained a medical qualification registrable in Great Britain

The University council has appointed Dr D R Hartree, lecturer in mathematical physics at the Cavendish Laboratory, to the Beyer chair of applied mathematics in succession to Prof E A Milne Dr Hartree was educated at Bedales School and at St John's College, Cambridge, of which he was an entrance scholar He took the Mathematical Tripos, Part I, in 1916, and the Natural Science Tripos, Part II (Physics), in 1922, his course being interrupted by the War With the rank of lieutenant, R N V R, he carried out research in ballistics and the calculation of high angle trajectories whilst in the Anti Aircraft Experimental Section of the Munitions Inventions Department He was elected to a fellowship of St John's College in 1922 and became a fellow of Christ's College in 1928

Calendar of Patent Records

March 17, 1693—During the seventeenth century there was a large number of patents granted in connexion with apparatus for working under water One such was granted to John Stapleton on Mar 17, 1693, for "a new engine soe by him contrived as to permitt a person inclosed in it to walk under water, and of a new invented way to force air into any depth of water to supply the person in the said engine therewith and for continuing a lamp burning under water, also a way to deserate and purifye the air so as to make the same serviceable for respiration" No further details of the apparatus are given

March 17, 1768—The art of making porcelain from native materials was unknown in England until William Cookworthy, chemist, of Bristol, discovered deposits of the requisite materials, kaolin and petuntse, in Cornwall and Devon Cookworthy was granted a patent for the manufacture on Mar 17, 1768, and established a factory at Plymouth, where the first china made of native clay was produced The patent was afterwards acquired by Richard Champion of Bristol, and was extended by Parliament

March 18, 1780—On Mar 18, 1780, there was granted to Louis Recordon, watchmaker, of London, the first patent for a self winding watch The re winding was effected by a heavily weighted but lightly balanced lever which was connected to the main spring spindle and was given sufficient motion to wind the spring by the ordinary movements of the wearer Breguet, the famous French watchmaker, made several watches with a similar device, and those that exist to day are said still to work satisfactorily

March 18, 1862—To Thomas Dunn, of Manchester, belongs the honour of having filed the largest patent specification This was lodged in connexion with his patent dated Mar 18, 1862, for "Improvements in the construction of bridges, roofs, houses, and other structures," and comprises 36 pages of description and 104 sheets of drawings It was printed at a total cost of more than £650, and formed a volume about 8 in thick which sold at the price of £2, 13s a copy The specification is very comprehensive, and includes the construction of bridges, reading rooms, floating fortifications, suspension roofs for railway stations, portable sheet metal buildings, churches, etc One of the most interesting proposals is the construction of elevated lattice work footbridges with spiral staircases which were especially designed to enable pedestrians to cross the busy streets of London, several examples of which are illustrated in the drawings Dunn was a prolific inventor, twenty three patents standing to his name in the printed indexes for improvements in machinery of all kinds

March 20, 1787—The practical application of machinery to the shearing of cloth, a necessary process preparatory to printing, is due to the Rev John Harmar, whose first patent for a cropping machine is dated Mar 20, 1787 In spite of a great deal of opposition the invention was extensively adopted, especially in the west of England, and was in use for many years

March 23, 1869—The synthesis of alizarin, the colouring matter of the root of the madder plant and the first of the natural dye stuffs to be produced artificially, was the work of Carl Liebermann and Carl Graebe of Berlin, who were granted a Prussian patent for five years for their invention on Mar 23, 1869 Commercial production of the synthetic alizarin was commenced the following year by the Badische Anilin und Sodafabrik by a process the English patent for which anticipated by one day an application from W H. Perkin for an identical process

Societies and Academies.

London

Royal Society, Mar 7—**T M Lowry and A G Nasini** The molecular dimensions of organic compounds Part 1 General considerations A comparative study of the physical properties of benzene with thiophen, toluene with a methylthiophen, benzene with cyclohexane, all pairs with similar boiling and freezing points, shows that the vapours exhibit regular increments rather than identity of properties, and the physical properties of the liquids and solids, depending on force fields of molecules as well as on dimensions, show still wider differences —**A G Nasini** The molecular dimensions of organic compounds Part 2 An apparatus, based on Rankine's method, has been constructed for measuring the viscosity of vapours, and Sutherland's constant and the mean collision area deduced for benzene and cyclohexane — Part 3 A further modification of the apparatus is described, in which a zero pressure is used on the condensation side of the capillary The viscosities of thiophen, methylthiophen and pyridine have been determined —**W A Bone and R P Frazer** A photographic investigation of flame movements in carbonic oxide-oxygen explosions A theoretical $2CO + O_2$ mixture is exploded at atmospheric pressure under varying conditions, such as 'dryness,' 'source and intensity of ignition,' as well as under the influence of superimposed 'shock waves' up to and including detonation The new Fraser high speed photographic machine was used Progressive drying reduces flame velocity and hinders combustion, but the hindering effect can be overcome by a strong electric field With superimposed 'shock waves' the speed at which a flame starts may be raised in successive abrupt steps until it attains a speed approaching that of the 'shock waves themselves'—**H S Patterson, R Whytlaw-Gray, and W Cawood** (1) Some observations on the condensation of water on smoke particles Particles of non hygroscopic smokes readily absorb water, thus increasing in size, if a small quantity of hydrogen chloride is present —(2) The process of coagulation in smokes Experimental graphs, especially for systems of low concentration, show distinct curvature in the direction indicated by theory Smokes which are most nearly homogeneous give coagulation graphs closely in agreement with Smoluchowski's theory as modified for aerial systems The smokes studied are formed by molecular collision rather than by condensation around pre existing nuclei —(3) The electrified particles in smokes A method has been worked out for counting directly charged and uncharged particles The particles of low temperature volatilisation smokes are initially almost entirely uncharged particles, but the proportion of charged particles rises rapidly Arc smokes and magnesium oxide smokes are highly charged from the start —(4) The structure of complex smoke particles Arc smokes often consist of aggregates of great complexity, composed of minute particles, while smokes produced by volatilisation at lower temperature have much simpler structure —**J G Semple** Cremona transformations of space of four dimensions by means of quadrics and the reverse transformations —**S Goldstein** On the vortex theory of screw propellers When the distribution of circulation along the blades of a screw propeller is such that, for a given thrust, the energy lost in the slip-stream is a minimum, then the flow far behind the propeller is the same as if the screw surface formed by the trailing vortices was rigid and moved backwards along its axis with a constant velocity —**O. W Richardson and P M Davidson** The spectrum of H_2: the

bands analogous to the parhelium line spectrum Part 2 The data give a spectroscopic ionisation potential of H_2 is 15 380 volts This compares with Pauli's value 23 7 volts on the old quantum mechanics and with 15 26 ± 0 13 estimated from Burrau's computations on the wave mechanics using Witmer's value of the heat of dissociation of H_2 —**R C Johnson** and **R K Asundi** A new band system of carbon monoxide Details are given of a new system corresponding to the transition $3'S \rightarrow 2'P$ —**I Waller** and **D R Hartree** On the intensity of total scattering of X rays General results due to Waller for radiation scattered by a many electron atom (neglecting 'relativity effects ') are used to give an approximate formula for intensity of total (coherent and incoherent) scattering of X rays —**C M White** Stream line flow through curved pipes A mathematical discussion indicating that for large disturbances, flow in curved pipes is more stable than flow in straight pipes, which is in opposition to the opinion that curvature tends to instability —**H A Wilson** The theory of cracking petroleum Calculations are based on theory of chemical equilibrium in mixtures of hydrocarbons discussed in previous papers When liquid fraction is greater than 50 per cent, calculated gasoline fraction is nearly independent of temperature and pressure, but depends on composition of oil When all oil is just vaporised the gasoline fraction is nearly the same in all cases Amount of oil cracked per day in a given reaction chamber at given temperature and pressure is inversely as gasoline fraction **A Fowler** The arc spectrum of silicon By passing an arc in nitrogen at atmospheric pressure, and using a vacuum spectrograph, the arc spectrum of silicon has been photographed to about λ1600 Comparison with singly ionised phosphorus, P II, shows the general similarity expected —**S F Grace** Internal friction in certain tidal currents —**T L Ibbs** and **A A Hirst** The thermal conductivity of gas mixtures —**D M Newitt, B J Byrne,** and **H W Strong** Equilibrium in the system methyl alcohol—hydrogen—carbonic oxide —**W A Bone, F R Weston,** and **D A Winter** Further experiments on the combustion of well dried carbon monoxide and oxygen mixtures Part 3 —**E K Rideal** and **O H Wansbrough-Jones** An investigation on the combustion of platinum —**R W Ditchburn** and **F L Arnot** The ionisation of potassium vapour —**H J Gough** and **H L Cox** The behaviour of a single crystal of zinc subjected to alternating torsional stresses —**F C Lea** The penetration of hydrogen into metal cathodes and its effect upon the tensile properties of the metals and resistance to repeated stresses —**W T Astbury** A new integrating photometer for X ray crystal reflections, etc —**T H Havelock** The dispersion of double refraction in quartz —**W L Bragg** The determination of parameters in crystal structures by means of Fourier series —**W G Bickley** Two dimensional potential problems concerning a single closed boundary —**P M S Blackett** On the design and use of a double camera for photographing artificial disintegration

Linnean Society, Feb 14 —**E E Edwards** On the morphology of the larva of *Dorcus parallelopipedus* L Apart from other characters, the larva of *Dorcus* can be separated from those of other European genera of Lucanidæ by the form and arrangement of the tubercles composing the coxæ and trochanteric stridulatory areas In its internal anatomy it exhibits affinities with certain genera of Scarabæidæ The nervous system is of an exceptionally primitive character as in *Lucanus*, and does not exhibit the great concentration of the ganglia of the ventral nerve cord prevalent in larvæ of the allied family Scarabæidæ —**A G Lowndes** Variation in Arctic freshwater Entomostraca Many species of freshwater Entomostraca are cosmopolitan in their distribution, and there appears to be no correlation between the difference in environments with variation shown by the separate species —**S R Bose** The biology of wood rotting fungi Viala's culture medium and sterilised wood blocks from which the air had been driven were used Sporophore formation occurred only in those cultures exposed to light, and was usually associated with poor vegetative growth When fruit bodies were formed, they usually occurred on the upper end of the slant towards the glass surface This is probably related to moisture conditions and the check of vegetative growth

CAMBRIDGE

Philosophical Society, Feb 11 —**T M Lowry** Configuration of quadrivalent atoms The evidence which led Werner in 1893 to assign a planar configuration to platinous salts of the type $[2NH_3 \; PtCl_2]$ is similar to that advanced by Vernon for tellurium and now disproved by Drew, who assigns to quadrivalent tellurium the same tetrahedral configuration as to sulphur X ray analysis however, has assigned a planar configuration to the anions of the tetragonal crystals of $K_2[PtCl_4]$, $K_2[PtCl_4]$ and $Am_2[PdCl_4]$ —**F G Mann** The stability of complex metallic salts αβγ Triamino propane co ordinates very firmly around the 6 co ordination octahedron, and in consequence divalent nickel, zinc, platinum and palladium all give salts containing the bis triaminopropane metallic complex $[\{NH_2 \; CH_2 \; CH(NH_2) \; CH_2 \; NH_2\}_2M]''$ Each metal has adopted the unusual (and in the case of divalent platinum, and palladium, quite abnormal) co ordination number of 6 in order to provide the octahedron necessary for maximum stability of the completed complex salt This accounts for their unexpected stability —**F H Constable** An apparatus for the study of gas reactions on electrically heated films of known area Electrodeposition on a graphite foundation, from a moving electrolyte, is used to produce metallic films The area is found by the interference method Carbon films are produced on graphite by the thermal decomposition of hydrocarbons While the area of a particular carbon film by the methylene blue adsorption method appears to be 6 8 times the plane area the area from sections drawn to scale showing irregularities greater than 5×10^{-4} cm is of the order of twice the apparent area **C P Snow** The structure of the nitric oxide molecule The vibration and rotation spectrum of nitric oxide has been studied upon a large infra red spectrometer specially designed for the analysis of bands into fine structure There is found to be one vibration band

PARIS

Academy of Sciences, Feb 4 —**Georges Claude** The utilisation of the thermal energy of the sea The experimental plant successfully operated last year at Ougrée is to be transferred to Cuba It is arranged to work on the difference of temperature between the temperature of the water at sea level and that at a depth of about 600 metres The tube will be two metres in diameter and two kilometres in length —**T A Janczewski** Theorems of oscillation for differential systems of the fourth order —**R Wavre** The problem of the figures of equilibrium of a fluid heterogeneous mass —**Joseph Pérès** The actions of a viscous fluid on an obstacle The case of the ellipsoid —**P Noaillon** Sketch of a new theory of the resistance of fluids —**Henri Malet** The propagation of light in the ether —**L Mallet** The ultra violet radiation of substances submitted to the gamma rays When pure liquids, such as water, are submitted

to the gamma high frequency radiation, light is emitted The continuous spectrum of this light appears to be limited by the natural absorption of the excited liquid —**Pierre Auger** The influence of the level of origin of the photoelectrons on the distribution in space of their initial directions —**A Boutaric** Remarks on the formulæ representing adsorption isotherms A comparison of tho formula of Freundlich and that of Jean Perrin —**Pierre Jolibois and Louis Chassevent** The reactions between colloidal silica and lime The reactions between silica and lime in solution are due to three phenomena, the coagulation of the silica by the lime, the combination of the lime and silica giving a hydrated calcium silicate, followed by adsorption of the lime In solutions rich in lime this adsorption continues for months —**R Bureau** The experimental study of the zones of silence in the propagation of short [wireless] waves As a provisional explanation, which further data may cause to be modified, it is suggested that the ionised layers of the upper atmosphere play the principal part but in certain critical cases a very slight modification may decide between two different paths through the ionised layers —**M and Mme A Chauchard** The influence of ischemia on the excitability of the cerebral cortex —**Maurice Fontaine** The increase in the consumption of oxygen by marine animals under the influence of high pressures Its variations as a function of intensity of compression —**Raymond-Hamet** The glucosides of *Digitalis purpurea* After a summary of the results obtained by various workers on the toxicity of commercial preparations from digitalis, an account is given of the direct comparison of the toxicity of crystallised digitaline (Nativelle) and pure digitoxine (Clœtta) From experiments on 120 dogs, the physiological activity of these two products was found to be identical —**Maurice Piettre** Some properties of serum albumen its crystallisation in the absence of any ionogenic element The application of tho acotone method, which permits tho analytical separation of the proteins and their preparation in the pure state, has solved the problem of the crystallisation of albumen, without any ionogenic element being present —**Marage** The choice of an ear trumpet —**Georges Blanc, J Caminopetros, J Dumas, and A Saenz** Experimental researches on the sensibility of the lower apes to the virus of dengue Various species were inoculated with the blood of men suffering from dengue None of the animals showed any clinical signs of the disease and there was no rise of temperature, but their blood, which was non virulent twenty four hours after inoculation, became virulent between the fifth and eighth days The apes thus treated were immune for at least fifty days

COPENHAGEN

Royal Danish Academy of Science and Letters, Oct 10 —**Niels Bohr** Quantum theory and relativity An examination of the difficulties brought to light by the attempts at reconciliation of the quantum postulate with the idea of relativity seems to require a further revision of our fundamental physical concepts as regards their application to atomic phenomena

Nov 2 —**Ejnar Hertzsprung** Proper motions of faint stars in the Pleiades Provisional results of an investigation in progress Comparison of old and new plates of the Pleiades taken at different observatories mainly in order to pick out the faint physical members of the group by aid of their common proper motion —**August Krogh** The biological assay of insulin After mentioning the degree of purity attainable in insulin preparations which is ascertainable by chemical assay, a comparison is given of biological methods

Nov 16 —**J N Brønsted** The kinetics of ethylene oxides The apparent basicity of ethylene oxides is explained on the basis of kinetic measurements in aqueous solutions of various composition It has been possible by these measurements to verify tho conclusions of recent theories on reaction velocity The results obtained have also some bearing upon the general problem of the nature of acids and bases

ROME

Royal National Academy of the Lincei, Nov 18 —**Gino Fano** Birational contact transformations of the plane —**U Cisotti** Concerning two recent notes by M Pascal and C Ferrari —**U Cisotti** Hydrodynamic actions in the proximity of salients —**A L Herrera** Investigations on the imitation of organised forms with albumen and mineral acids (2) Further structures resembling those of unicellar organisms or of cellular tissues are described The forms obtained exhibit no evolution or motion, they may be stained with hæmotoxylin and preserved in glycerol —**R Calapso** A transformation of the surface R —**R Caccioppoli** The expression of the area of a surface by means of a doublo integral —**Silvia Martis in Biddau** Calculation of the logarithm of a matrix of the second order, and its application to the study of groups of one parameter containing a given substitution —**V Glivenko** The probable values of functions —**E Cech** Asymptotic correspondences between two surfaces —**E Pistolesi** Further with regard to the Kutta Joukowski theorem in the case of the plane strip —**G Viola** Elliptical elements of the system of U Ophiuchi —**A Carrelli** The theory of sensitised fluorescence A treatment is given of the phenomenon of sensitised fluorescence on the basis of undulatory mechanics, the method followed being that by which Born elaborated the theory of inelastic shock between the electron and the material atom —**V Polara** Gibbs theorem (phase rule) for heterogeneous equilibria —**G Bargellini** 2 6 Dichlorophenetidine The results of earlier experiments indicated that the dichlorophenetidine prepared by Jaeger by passing hydrogen chloride through an alcoholic solution of p nitrosophenol is probably the 3 5, but possibly the 2 6 compound The latter has now been prepared in another way and proves to be different from Jaeger's compound, which is therefore 3 5 dichlorophenetidine —**G Mezzadroli and E Vareton** Influence of metallic magnesium on the formation of formaldehyde and sugars by the action of ultra violet rays on solutions of calcium bicarbonate The reducing power (towards iodine solution) developed on exposing calcium bicarbonate solutions to ultra violet rays attains a maximum after 30 minutes if open basins, or after an hour, if closed vessels of transparent quartz are used, the yield of reducing substances is higher in the latter case The presence of metallic magnesium in the solutions increases the total quantity of reducing substances formed, and induces the formation of sugars capable of reducing Fehling's solution and of giving an osazone —**G Spagnol** Experiments on the fixation of colloids caused by chloroform If colloidal mercuric sulphide is injected into the auricular vein of a rabbit and a wad of cotton wool soaked in chloroform is simultaneously applied for 15 seconds to the animal's side, a sharp black stain of the sulphide is found in the subcutaneous connective tissue under the chloroformed spot when the rabbit is killed—after 2 hours or 8 days Similar fixation of Trypan blue is observed —**A Desio** Presence of the miocene in Sirtica —**G Brunelli** The epoch of reproduction of *Delphinus* —**M Tirelli** Studies on the physiology of insects (nervous system) —**A Barchiesi** Histophysiological investigations on the influence of variations of temperature in certain organs of heterotherms

Diary of Societies

FRIDAY, MARCH 15

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botanical Lecture Theatre Imperial College of Science and Technology) at 2.30 —Sir John Russell Some Agricultural Problems in Australia.—F L. McDougall The Commonwealth Council of Science and Industry in its Relation to Agriculture

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 4 30.—Thunderstorms and the Maintenance of the Earth s Electric Field Chairman, Prof S Chapman Discussion to be opened by Prof E V Appleton and continued by R. A. Watson Watt Dr G C Simpson Prof C T R Wilson, and T W Wormell

BIOCHEMICAL SOCIETY (Annual General Meeting) (in Department of Physiology and Biochemistry University College), at 4 30 —I S MacLean Further Observations on the Sterols of Yeast.—H J Channon and A C Chibnall The Isolation of n nonacosane and di n tetradecyl Ketone from Cabbage Fat —J G Davis and A T R. Mattick The Metabolism of a Pigmenting Anaerobic Bacterium —G N Richardson and R K. Cannan Reaction of Azine Compounds with Proteolytic Enzymes —B C Guha and Prof J C Drummond Observations on the Concentration of Vitamin B_1 —Prof J C Drummond R. A. Morton, and K H Coward A Critical Examination of the Methods for the Assay of Vitamin A.—C R Harington and S S. Randall Isolation of 3 5-diiodotyrosine from the Thyroid Gland

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION (Annual General Meeting) (at Society of Medical Officers of Health, 1 Upper Montague Street) at 5 —Sir Henry Gauvain The Combined Education of Children Suffering from Physical Defects

BRITISH INSTITUTE OF RADIOLOGY (Medical Meeting), at 5 —Discussion on Urinary Cases

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Sir Arthur Keith Demonstration of Recent Advances in our Knowledge of the Anatomy and Physiology of the Gall Bladder

BRITISH PSYCHOLOGICAL SOCIETY (Æsthetics Section) (at Bedford College), at 5 30 — Mrs. Roberts (Susan Miles) and others Discussion on Inspiration.

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (Annual Meeting) (at Liverpool University), at 6.—L. O Newton Boiler Feed Water

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—F C Johansen Research in Mechanical Engineering by Small Scale Apparatus.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Newcastle-upon Tyne), at 6.—J H. Gibson Mechanical and Transmission Losses in Marine Engines Shafting, and Propellers.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section), at 6.15 —C F J Morgan Wave form Analysis.

ROYAL AERONAUTICAL SOCIETY (at 7 Albemarle Street), at 6.30 —L. T Brown The Napier Lion Engine

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) (at Glasgow), at 6 45 —Annual Meeting

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (Annual General Meeting) (at Cardiff Technical College), at 7 —T G Watts The Co-ordination of Chemical Industry and Chemical Societies.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group) at 7

SOCIETY OF DYERS AND COLOURISTS (Glasgow Section) (at 7 Gordon Street, Glasgow), at 7 15 —F Asquith The Necessity of Application of Fast Colours on Textile Fabrics.

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7 30—T Grime Locomotive Rating

ROYAL SANITARY INSTITUTE (at Town Hall, Torquay), at 8 —G J Loveless The Plumber and Public Health

ROYAL SOCIETY OF MEDICINE (Obstetrics Section) (jointly with Maternity and Child Welfare Group of the Society of Medical Officers of Health), at 8 —Discussion on The Future of the Maternity Services —Openers for Section of Obstetrics Prof J M M Kerr and E. Holland.—Openers for Society of Medical Officers of Health Dr E Hill and Dr J J Buchan

ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8 30 — Dr W S Whitcombe Intensive Ionisation —Dr A B MacLean The Prone Position as a Routine Method in the X ray Examination of the Stomach, with a Note on the Question of Retractability of the Stomach.

ROYAL INSTITUTION OF GREAT BRITAIN at 9 —Prof V M Goldschmidt The Distribution of the Chemical Elements.

SOCIETY OF DYERS AND COLOURISTS (Manchester Section) — Short Papers

SATURDAY MARCH 16

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (South Midland District) (at Uxbridge), at 10 30 A M

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (South Western District) (at Guildhall Bath), at 11 A M —Annual District Meeting

BRITISH MYCOLOGICAL SOCIETY (at University College), at 11 —C R. Metcalfe Shab Disease of Lavender —Dr G H Pethybridge Exhibit of an Unusual Hypertrophy in Potato Tubers due to *Spongospora*.—Miss K Sampson Some Observations on *Epichloe typhina* (Pers) Tul —R. S. Vasudeva On the Parasitic Invasion of Apple Fruit by Various Fungi —W R D Weston The Relative Resistance of some Wheat Varieties to *Tilletia caries* (DC) Tul (T Tritici Wint)

PHYSIOLOGICAL SOCIETY (Annual General Meeting) (at University College), at 3 —M C G Israels and F W Lamb Carbon Dioxide Equilibria between Mixed Venous Blood and Rebreathed Airs —Dr J S Haldane Claude Bernard s Conception of the Internal Environment.—A Hemingway and J M Peterson The Action of Oxytocin and Vasopressin on the Perfused Isolated Kidney —Prof R. S S McDowall The Central Chemical Control of the Heart Rate —A I Gorer and M S Pembrey Observations upon the Respiratory Exchange of Hibernating Mammals —R. E Havard and I M T Kerridge A Change in the Hydrogen Ion Concentration of Blood after Shedding —Ruth Deansley The Effect of Toxins on the Adrenal Gland —G F Marrian The Assay of Œstrin —A. R Fee and Dr A S Parkes The Mechanism of Ovulation in the Rabbit.—A R Fee Experimental Water Diuresis —A R Fee and E Ogden Physiological Significance of the Renal Portal System —E Leyko The Action of some Heart Tonics —E Leyko and J Mehes The Action of Ephedrine —J P Bouckaert Efficiency and Fenn Effect in Tortoise Muscles —J P Bouckaert F Cappellen and J De Blende Value and Significance of the Constants of Muscle Viscosity —H Florey A. Szent-Gyorgyi and M E Florey Methods for Testing for the Presence of Adrenal Cortex Hormone —M Grace Eggleton and Prof C Lovatt Evans The Formation and Disappearance of Lactic Acid —Demonstrations —M C G Israels and F W Lamb A Modified Henderson Automatic Sampler for Alveolar Air — F W H Ellis (a) A Water Driven Centrifuge (b) Variable Speed Gear (c) Artificial Lung with Bakerlite Plates (Bayliss Fee and Ogden) (d) A Perfusion Tap (e) Perfected Roller Pump (Bayliss).— G E S Ward and S Wright Human Electrocardiographic Curves During and After Nitrous Oxide Anæsthesia.—Dr B A McSwiney A Frog s Heart Chamber —A. R. Fee and Dr A S. Parkes The Effect of Hypophysectomy (by Decerebration) on Ovulation in the Rabbit — J P Bouckaert Apparatus for Measuring Muscle Viscosity Extension time Curve —F Gairns Microscopic Demonstration of Nerve Endings —Prof A V Hill The Increment due to Stimulation in the Resting Anaerobic Heat-Rate of Muscle —R I Lythgoe (a) Test Types (b) Apparatus for Study of Visual Acuity (Mezzanine)—W S. Duke Elder P M Duke Elder and J Colle The Optical Registration of the Intra ocular Pressure —E Bozler The Heat Production of Smooth Muscle —F R. Winton A Thermostat Constant to One thousandth of a Degree Centigrade at Body Temperature

ROYAL INSTITUTION OF GREAT BRITAIN at 3 —Sir Ernest Rutherford Molecular Motions in Rarefied Gases (III)

GEOLOGISTS ASSOCIATION (North East Lancashire Group) (at Blackburn Technical College) at 7 —J Ranson The Evolution of the Craven Highland

HULL ASSOCIATION OF ENGINEERS (at Technical College Hull) at 7 15 — G E Petty Aeroplane Design

MONDAY MARCH 18

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4 30 —Rev A H Finn Conjectural Emendations in the Psalms

ROYAL COLLEGE OF SURGEONS OF ENGLAND at 5 —C E Shattock Demonstration of Specimens Illustrating Diseases of the Testis

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6 30.— M Isacco The Helicogyre.

INSTITUTION OF MECHANICAL ENGINEERS (Graduates Section London), at 6 30 —K Brinsmead Locomotive Lubrication

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7 —C Turnbull and others Discussion on Method in Invention

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7 —E Y Robinson Radio Sets on the Mains.

BRADFORD TEXTILE SOCIETY (at Midland Hotel Bradford), at 7 30 — W Bell Banking and Commerce

HUDDERSFIELD TEXTILE SOCIETY (at Huddersfield Technical College) at 7 30 —H Wilkinson The Practical Routine of Piece Dyeing

SOCIETY OF CHEMICAL INDUSTRY AND INSTITUTE OF CHEMISTRY (Edinburgh and East of Scotland Sections) (at 36 York Place Edinburgh), at 8 — J A Reavell Heat Transmission

CHEMICAL INDUSTRY CLUB, at 8.—Dr C Singer Hygiene and History

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30 —O G S Crawford Air Photographs of the Middle East

TUESDAY, MARCH 19

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5 —Dr R. A Young A Medical Review of the Surgery of the Chest (Lumleian Lectures) (I).

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Dr S. W Kemp Antarctic Whaling Expeditions (II).

Mineralogical Society, at 5.30.—A. W. Groves and A. E. Mourant: Inclusions in the Apatites of some Igneous Rocks.—L. A. Narayana Iyer: Calc-gneisses and Cordierite-sillimanite gneisses of Coimbatore, Madras Pres., and of Similar Occurrences in India.—F. A. Bannister: A Relation between the Density and Refractive Index of Silicate Glasses with Application to the Determination of Imitation Gem-stones.

Royal Society of Medicine (General Meeting), at 5.30.

Zoological Society of London, at 5.30.—Dr. C. J. Van der Klaauw: On the Development of the Tympanic Region of the Skull of the Macroscelididæ.—Lilian Russell: The Comparative Morphology of the Elysioid and Æolidioid Types of the Molluscan Nervous System and its Bearing on the Relationships of the Ascoglossan Nudibranchs.—S. Maulik: On the Structure of the Hind Femur of Halticine Beetles.—J. W. Winterbottom: Studies in Sexual Phenomena—Communal Display in Birds.—Capt. C. R. S. Pitman: Notes on the Vertebrate Fauna of Nkosi Island, Lake Victoria, Uganda, Africa.

Institution of Civil Engineers, at 6.

Institution of Electrical Engineers (South Midland Centre) (jointly with East Midland Sub-Centre) (at Loughborough Town Hall), at 6.45.—H. B. Atkinson: How Electricity does Things (Faraday Lecture).

Electrical Association for Women (at 15 Savoy Street), at 7.—H. Bourne: Some Elementary Facts concerning Electric Motors.

Institution of Electrical Engineers (North Western Centre) (at Engineers' Club, Manchester), at 7.—T. N. Riley and T. R. Scott: Electrical Insulating Papers for the Manufacture of Power Cables.—S. G. Brown and P. A. Sporing: The Prevention of Ionisation in Impregnated Paper Dielectrics.

Institution of Heating and Ventilating Engineers (Associate Members and Graduates Branch) (at Milton Hall, Manchester), at 7.—A. E. Cubbage: Address.

Illuminating Engineering Society (at 15 Savoy Street), at 7.—W. Maitland: Architectural Lighting.

Royal Photographic Society of Great Britain (Kinematograph Group), at 7.—E. E. Lamb: Demonstration of Bell and Howell Kinematograph Cameras and Projectors.—B. W. Hanchett: A New System of Studio Lighting for Panchromatic Film, with Mercury Vapour Lamps.

Institute of Metals (Birmingham Local Section) (at Engineers' Club, Birmingham), at 7.—Dr. N. F. Budgen: Aluminium.

Institute of Metals (North East Coast Local Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.—Annual General Meeting and Exhibition.

Institution of Automobile Engineers (Inventors' Evening) (at 83 Pall Mall), at 7.45.

Manchester Athenæum Textile Society (at Manchester).—H. P. Curtis: Cloth Faults.

WEDNESDAY, March 20

Institution of Naval Architects (Annual Meeting) (at Royal Society of Arts), at 11.—Admiral of the Fleet Lord Wester Wemyss: Presidential Address.—Sir William J. Berry: H.M. Battleships *Nelson* and *Rodney*.—Lieut.-Col. F. Doudoni: Sea Trials of Italian Destroyers.

Institution of Chemical Engineers (Annual Corporate Meeting) (at Grosvenor House, Park Lane), at 12.15.—Sir Alexander Gibb: The Co-ordination of Engineering Institutions and Societies (Presidential Address).—At 2.15.—Prof. B. P. Haigh: Chemical Action in Relation to Fatigue in Metals.

Society of Glass Technology (at Leeds University), at 2.30.

Geological Society of London, at 5.30.—Sir Douglas Mawson: Some South Australian Algal Limestones in Process of Formation.—Dr. A. W. Groves: The Unroofing of the Dartmoor Granite and an Outline of the Distribution of the Detritus in the Sediments of Southern England.

Institution of Electrical Engineers (Tees-Side Sub-Centre) (at Cleveland Technical Institute, Middlesbrough), at 7.—R. W. Gregory: Electric Supply to the Rural Districts of England.

Textile Institute (London Section), at 7.—H. Clayton and others: Informal Discussion on Fabric Printing.

Institution of Electrical Engineers (Sheffield Sub-Centre) (in Mappin Hall, Sheffield), at 7.30.—Prof. W. Cramp: The Cause and Effect of Oscillation in Electrical and Mechanical Apparatus.

Royal Meteorological Society, at 7.30.—R. A. Watson Watt: Weather and Wireless (G. J. Symons Memorial Lecture).

Royal Microscopical Society, at 7.30.—Capt. M. A. Ainslie, C. Beck, J. W. Gordon, Sir Herbert Jackson, Prof. A. W. Porter, and J. Rheinberg: Discussion on paper by Dr. H. Moore on The Mode of Formation of the Image in the Microscope.

Royal Society of Arts, at 8.—Prof. A. E. Richardson: Modern English Architecture.

Entomological Society of London, at 8.

Royal Society of Medicine, at 9.15.—Dr. I. Williams: Napoleon III.

THURSDAY, March 21

Institution of Naval Architects (Annual Meeting) (at Royal Society of Arts), at 11.—J. Johnson: The Propulsion of Ships by Modern Steam Machinery.—Dr. J. Bruhn: Some Considerations Regarding International Loadline Regulations.—At 3.—Dr. G. Kempf: New Results Obtained in Measuring Frictional Resistance.—C. F. A. Fyfe: The Practical Use of the First British Built Bauer-Wach Exhaust Steam Turbine Installation in the Booth Liner *Boniface*.—At 8 P.M.—Prof. C. E. Inglis: Natural Frequencies and Modes of Vibration in Beams of Non-Uniform Mass and Section.—S. A. Hodges: The Behaviour of Stiffened Thin Plating under Water Pressure.

Chemical Society (Annual General Meeting) (at Leeds University), at 4.30.—Prof. J. F. Thorpe: Co-operation in Science and Industry (Presidential Address).

Royal Society of Medicine (Dermatology and Epidemiology Sections), at 4.45.—Special Discussion: Industrial Dermatoses, their Causation, Recognition, Prevention, and Treatment.

Royal College of Physicians of London, at 5.—Dr. R. A. Young: A Medical Review of the Surgery of the Chest (Lumleian Lectures) (II.).

Royal Institution of Great Britain, at 5.15.—Rev. W. H. Draper: Change of Meaning of Words from One Period to Another.

Institution of Mining and Metallurgy (at Geological Society), at 5.30.

Institution of Electrical Engineers, at 6.—Hon. Sir Charles A. Parsons and J. Rosen: Direct Generation of Alternating Currents at High Voltages.—J. A. Kuyser: Recent Developments in Turbo-Generators.

Institution of the Rubber Industry (Manchester and District Section) (at St. Mary's Parsonage, Manchester), at 7.—Dr. G. Barr: Ageing of Cotton contained in Rubber Goods.

Institution of Automobile Engineers (Western Centre) (at Technical School, Gloucester), at 7.30.—L. W. Johnson: The Inspection of Metals and their Alloys.

Batley and District Textile Society (at Public Library, Batley), at 7.30.—J. Brooke: Practical Hints on Carding.

Royal Society of Tropical Medicine and Hygiene (Laboratory Meeting) (at Royal Army Medical College), at 8.15.—Demonstrations by Dr. Mary Andrews, Major E. E. Austen, Major H. C. Brown, Dr. W. T. C. Broom, Major S. Elliott, Dr. E. Hindle, Dr. A. C. Stevenson, Col. S. P. James, Col. W. P. MacArthur, Dr. J. C. Ray, Major D. T. Richardson, and Dr. V. B. Wigglesworth.

Royal Society of Medicine (Urology, Pathology, and Therapeutics Sections), at 8.30.—Special Discussion: Urinary Antiseptics.

FRIDAY, March 22

Institution of Naval Architects (Annual Meeting) (at Royal Society of Arts), at 11.—Eng. Rear-Admiral W. Scott-Hill: Powdered Coal for Ships.—A. Spyer: Modern Developments of the Water Tube Boiler for Marine Purposes.—Eng. Rear-Admiral A. E. Hyne: Suggested Modifications to Marine Water Tube Boilers.—At 3.—J. Rennie Barnett: Motor Life-Boats of the Royal National Life-Boat Institution.

Textile Institute (Lancashire Section) (at Manchester), at 1.15.—J. W. Cooling: Air Conditioning Apparatus including Humidifying and De-Humidifying.

Royal Society of Medicine (Disease in Children Section) (Clinical Meeting at Royal Free Hospital), at 4.30.

Physical Society (Annual General Meeting) (at Imperial College of Science), at 5.—Dr. W. H. Eccles: Presidential Address.

Royal College of Surgeons of England, at 5.—Sir Arthur Keith: Demonstration on the Nerve Supply and Movements of the Colon.

Institute of Marine Engineers, at 6.30.—Annual General Meeting.

Institution of Locomotive Engineers (North Eastern Centre) (at Hotel Metropole, Leeds), at 7.—T. Robson: Experiments on Buffer Springs.

Royal Photographic Society of Great Britain, at 7.—H. Lambert: Warm Tones on Chloro-Bromide Papers.

West of Scotland Iron and Steel Institute (Annual General Meeting) (at Royal Technical College, Glasgow), at 7.—F. G. Martin: Elastic Limit Steel.

Blackburn Textile Society (at Blackburn Technical College), at 7.30.—A. J. Hall: The Dyeing and Finishing of Cotton Piece Goods containing Artificial Silk.

Leicester Textile Society (at Victoria Hall, Leicester), at 7.30.—S. Kershaw: Faults in Yarns.

Junior Institution of Engineers (Informal Meeting), at 7.30.—D. A. Collin: Ventilation.

Royal Institution of Great Britain, at 9.—Sir Ernest Rutherford: Penetrating Radiations.

SATURDAY, March 23

Royal Institution of Great Britain, at 3.—Sir Ernest Rutherford: Molecular Motions in Rarefied Gases (IV.).

PUBLIC LECTURES

SATURDAY, March 16

Horniman Museum (Forest Hill), at 3.30.—J. R. S. Dallas: Saxon Churches and their Remnants.

MONDAY, March 18

East Anglian Institute of Agriculture (Chelmsford), at 7.—W. R. Dunlop: The Economy of Labour in Farming.

TUESDAY, March 19

Bedford College, at 5.15.—Sir Herbert Baker: Modern Tendencies in Architecture.

SATURDAY, March 23

Horniman Museum (Forest Hill), at 3.30.—M. A. Phillips: Mammals of Britain.

DISCUSSION

Friday, March 15

Faraday Society (at Chemical Society), at 2.30 and 4.30 (*continued from March* 14).—Crystal Structure and Chemical Constitution:—

Part II. Organic Compounds.—Sir William Bragg: Introduction.—Dr. A. Müller: A Hydrocarbon Model.—Dr. H. S. Piper: Limitations in the Method of Identifying Long Chain Compounds by a Measurement of their Spacings.—Mrs. K. Lonsdale: X-ray Evidence on the Structure of the Benzene Nucleus.

Part III. Metals.—Dr. J. D. Bernal: The Problem of the Metallic State.—Prof. A. F. Westgren and G. Phragmén: X-ray Studies on Alloys.

Part IV. General.—Prof. A. Reis: On the Intensity, Sharpness, and Reducibility of the Debye-Scheerer Lines.—Prof. H. Mark: The Methods of Determining the Size and Shape of Small Crystals.—Dr. K. Weissenberg: Lattice Determination in Polycrystalline Aggregates.—Dr. W. T. Astbury: An Integrating Photometer for X-ray Crystal Reflections.—Dr. N. H. Kolkmeijer: Allotropy and the Determination of Densities by X-rays.—Prof. P. P. Ewald: Report on Recent Developments of Wave Mechanics and its Bearing on Crystal Structure.

SATURDAY, MARCH 23, 1929.

The National Museums at South Kensington

WE dealt last week with the position of the Natural History Museum at South Kensington in relation to the Trustees of the British Museum at Bloomsbury, of which it is a branch There are eventually to be three museums at South Kensington, and it seems to be desirable that these should be under a single authority interested in the advancement of natural knowledge and its utilisation for the good of the nation The Interim Report of the Royal Commission on National Museums and Galleries leaves open the whole question of the governance of the national collections, both of museums and of public galleries The internal control of such institutions and their staffs by directors is clearly a desirable arrangement, but their interrelationships, policy, and development are as certainly matters of public concern The director is responsible to a Minister, where national funds are concerned, but there is usually some body between, either in a governing or in an advisory capacity The collections include countless gifts and bequests to the nation, and the nation is the trustee for these Each gift entails annual expenditure, be it book, picture, machine, or animal, and staffs have to be maintained to care for them, and to see that they are available for the study of experts and for the education and intellectual amusements of the public Catalogues have to be printed, and special exhibitions arranged, and these do not usually pay for themselves In addition, certain institutions are so clearly connected with industry and commerce, on which the country and empire so closely live, that annual expenditure is requisite for additions and for the study of these

The Museum of Practical Geology is the central institution concerned with the mineral wealth of Great Britain and with the nature of the land on which we live and build, and off which we have to obtain our water By its staff it conducts the Geological Survey in the field, and its Museum is open to the public for reference and advice The practical application of science to engineering, mining, manufacturing of every sort, and to building construction is the charge of the Science Museum, and its exhibits are judiciously designed to help these The British Museum of Natural History is, on one hand, of great intellectual value, while on the other, it deals with raw animal products both for food and industry It is a central reference station for economic biologists and is deeply concerned with the insect and other animal pests which

attack plants and animals It also has its plant department, while the practical institution for plant products is furnished by the Royal Botanic Gardens at Kew

These institutions have one characteristic in common, namely, that they are connected with one class of mankind whose sole aim is the increase of natural knowledge, and with a second larger class whose business it is to apply that knowledge to the development of the world In a word, they are scientific, and their directorates and staff belong to a group of men who are accustomed to act together in mixed societies in particular in the Royal Society, and in universities The secret of their successful co operation lies in their common basic training in respect to natural phenomena, this resulting in a peculiarly impersonal mode of examining any problem presented to them Year by year they become less separable, since most natural phenomena entail knowledge of two or more 'sciences,' and research year by year is shifting to border lines The relation of these Museums to one another and to the State deserves careful consideration, for it is obvious that they must continue to grow and progress *pari passu* with the evolution of the country and of the Empire They can no longer be considered as apart from national prosperity, for they are factors directed to assuring that prosperity, and the cost of their upkeep is a trifling premium Ideally, they must be in contact with the highest minds in their sciences and with the most interested industrialists

The position of these four foundations is that they report to and are under the financial control of four different Departments of State The Royal Botanic Gardens, Kew, are included in the parliamentary vote of the Ministry of Agriculture and Fisheries, and there is no 'governing body' other than the Minister They are not to be regarded as primarily connected with British agriculture and horticulture, for which other institutions specialise, but with the increase of the basal practical knowledge of plant growth Their staff is largely concerned with economic interests and research that are imperial in character Indeed, Kew is a central bureau in all such matters for all the dominions The herbarium is largely built up of the type collections of colonies and is essential for reference in such work Distinguished and wise directors have succeeded each other for so long that the director is as nearly independent as any Government servant can be As plant products have to be grown with an understood relationship to their method of treatment or manufacture—the business of the Science Museum—there is a slight overlapping, but this is not altogether a disadvantage We think, therefore, that Kew may be left independent of the scheme we have in mind for the Natural History, Science, and Geological Museums

These three museums are to be topographically connected with each other in the same block at South Kensington, since the Geological Museum is to be removed to a site there in close communication with the other two At present it is under the Department of Scientific and Industrial Research, which also has control of the National Physical Laboratory, as well as of numerous research boards connected with industry A committee of the Privy Council, representing many State Departments and all political parties, constitutes this Department under the Lord President and it is assisted by an Advisory Council, the members of which clearly are principally concerned with its activities in fields other than geology The detailed supervision of the work is in the hands of a competent committee of the Department The specimens displayed in this Museum are similar to those shown in the Natural History Museum, but they are arranged differently, as indeed is essential The palæontological workers are experts of the same order, and clearly the freest possible interchange and the closest relationship between these Museums is likely to be to the advantage of both The mineralogical collection of the Natural History Museum might be developed to illustrate more clearly the study of rocks, while it is surely the function of the Science Museum to elucidate physical geology

The Science Museum was a most interesting experiment, which after a chequered existence for half a century, seems to be likely to have a brilliant future in respect both to pure science and to industry It has a close connexion with the products of art, but clearly its fundamental relationship is in respect to the utilisation of the raw products, with which its neighbours are concerned The Royal Commission is clearly in agreement, since it has suggested a grant for a conference hall for discussions between industry and science, while it is pointed out that a common lecture theatre is an important need Here the Museum is under the Minister of Education, whose main interest obviously must be elsewhere and whose appointment must have been largely political There is an Advisory Council of technical and scientific men, it is true, but the members of such *purely advisory* bodies can scarcely be expected to display

that personal responsibility, the sense of which to a large degree ensures impartiality

The present seems the favourable moment for the consideration of these national museums as an organic whole We have in being a Royal Commission, the Interim Report of which shows a rare appreciation of the educational and industrial scope of these institutions, together with a fearless handling of the financial problems related to the guardianship of the public purse We believe that that essential to all governance, cheerful consent of the governed, would be found to exist were the Commission to propose a scheme which would bring the three scientific museums at South Kensington under one system of control Thus most easily can uniformity in rate of pay and in promotion in relationship to other scientific posts in the country be obtained The extraordinarily rapid changes in both science and industry necessitate the governance by experts from all sides in the closest relationship to one another, and they must be led to feel their personal responsibility Such a result can scarcely be brought about by handing these museums to an overworked Government department, controlled necessarily by experts in one direction The whole country, not one city, pays for these institutions, and their policy and development must be in the direction of national and imperial interests, the concern of many departments

Our system demands a relationship to one Minister, and, failing the direct interest of the Prime Minister, which it is too much to expect, the connexion is perhaps closest with the Lord President of the Council, who is selected for his wisdom in affairs and for his wide sympathy with every phase of national development Under this Minister there would have to be the governing body, with access to him, and with full power to report to him, and in practice to settle the policies of the museums so far as funds allow It would act through committees for each institution, with perhaps a single annual meeting of the whole body Only advantage can result from the freest discussion of policy between experts in science and industry—and unquestionably the greater and more practical men of science, as the directors of these museums must be, are happy in the discussion and justification of their views and desires for the advancement of knowledge The success of such an authority depends on the intelligence and disinterestedness of its members, qualities well displayed by the Royal Commission, which can examine many precedents and will, we trust, make specific recommendations

Greenland under Danish Rule

Greenland Published by the Commission for the Direction of the Geological and Geographical Investigations in Greenland Editors Prof M Vahl, Vice Admiral G C Amdrup, Dr L Bobé, Prof Ad S Jensen Vol 1 *The Discovery of Greenland, Exploration and Nature of the Country* Pp vii + 575 (London Oxford University Press, Copenhagen C A Reitzel, 1928) 40s net 3 vols, 100s net

HANS EGEDE landed in Greenland in 1721 for three centuries the Norse colonies had been lost , and Egede's landing was therefore the beginning of a new era of Scandinavian over lordship The missionary himself wrote a description of the country and its native inhabitants, published in Danish in 1741, and translated into English four years later There have been other general accounts, but the latest and perhaps the best known is Dr Rink s Danish Greenland," which appeared in 1877 Early in the following year the Danish Government authorised the formation of a Commission for the Direction of the Geological and Geographical Investigations in Greenland publications under the title ' Meddelelser om Grönland " began in 1879, and there are now no less than seventy volumes of this well known series In more recent years, therefore, the position has been that those wishing to obtain first hand and up to date information could only do so by searching through the seventy volumes of the "Meddelelser " The work under review is definitely meant to remove this difficulty Essentially it is a summary and co ordination of the fifty years' research contained in the " Meddelelser " It is hoped to complete it in three volumes in 1929 the present deals with the discovery, exploration, and general nature of the country , the second with the past and present population , and the third with the colonisation and history

Primarily the book is intended for officials and travellers in the country itself As a work of reference it will be quite indispensable Apart from this it is exceedingly well written, and abundantly illustrated with photographs and maps , few countries are so fortunate , it is not too much to say that this is a book to be recommended not only to those closely interested in Greenland, but also to those with slighter interests but appreciation of geographical literature well written and well produced Its nature is general rather than detailed In this connexion it should be noted that minute details, district by district, were published

in 1921 in Danish, under the title "Grönland i Tohundredaaret for Hans Egedes Landing," two volumes and atlas The completion first of the Danish work and now of its English complement will thus round off the intention of the Danish Administration, which, by undertaking these two publications, desired to mark in the most suitable way the bicentenary of Danish rule

The compilers of the present volume are for the most part well known geographers, geologists, and biologists To each has been assigned a particular division, either a physiographical account of one of the coasts, or articles on the flora, on the geology, and so on To some of the latter articles the position of Greenland, as a bridge between Europe and America, gives important significance For example, Prof Ostenfeld traces the origin of the different flowering plants, and finds that about one fifth are European, whilst the remainder (316 species) must be supposed to be of American origin, or for the smaller part to have survived the maximum of the Glacial Period in Greenland He strongly favours the survival of the hardiest species throughout the maximum glaciation, and as evidence points to the present condition on certain of the nunataks

In recent years the interest of geologists has been directed to the need of fuller knowledge of the stratigraphy and tectonics of Greenland, and this to English readers will give more than usual interest to the articles by Prof Bøggild on the geology of the country as a whole and by Dr Lauge Koch on the physiography of the northern part In Dr Koch's article will be found an account of the Caledonian folds of the extreme north west, from North Greenland these folds are marked as passing into Ellesmere Land, and their ultimate fate is therefore a problem for Canadian geologists The folding is regarded as the continuation of our own Caledonian chain via Norway and Spitsbergen, a conclusion which most will accept, though it should be noted that, while the North Greenland folds are well authenticated by fossil evidence, such can scarcely be claimed as fully proved as yet in the Spitsbergen (Hecla Hook) portion of the chain The further problem of the relationship of Koch's Caledonian Chain with the great thickness of disturbed Lower Palæozoic rocks in East Greenland, which according to Prof Bøggild run for nearly 300 miles from Queen Louise's Land to Davy Sound, has yet to be settled Here also there would appear to be Caledonian folds, and so disposed that their relationship to the Scottish North-west Highlands may be of considerable importance to the geological history of Britain

It would perhaps be invidious to select special articles without stressing the exceptional value of the book as a whole one is tempted, however, to refer to Dr Birket Smith's most able and interesting account of West Greenland physiography The article may be cited as typical of the extreme care and judgment shown by all the contributors, rash conclusions and theories are almost entirely absent, and the body of the work is essentially a collection and marshalling into proper order of the data of scientific observation By itself alone this first volume is evidence of the foresight and wisdom of the Danish Administration in Greenland, and, when complete, the work should constitute a most impressive proof of the disinterestedness of Danish rule during the last two hundred years

Cohesion, Viscosity, and Lubrication

(1) *Cohesion and related Problems a General Discussion held by the Faraday Society, November 1927* Pp 49 180 + 5 plates (London The Faraday Society, 1928) 10s 6d net

(2) *Studies in Molecular Force* By Dr Herbert Chatley (Griffin's Scientific Text Books) Pp xi + 118 (London Charles Griffin and Co, Ltd, 1928) 7s 6d net

(3) *The Viscosity of Liquids* By Emil Hatschek (International Text Books of Exact Science) Pp xii + 239 (London G Bell and Sons, Ltd, 1928) 15s net

(4) *The Theory of Film Lubrication* By R O Boswall Pp xi + 280 (London, New York and Toronto Longmans, Green and Co, Ltd, 1928) 12s 6d net

NO property of matter is more obvious, or of more continual importance, than cohesional force These four volumes deal with many aspects of its study, and of the practical application of our knowledge

(1) The Faraday Society "Discussion" presents fifteen papers, about half of which deal wholly or partially with the question of why matter in bulk breaks under a stress many times less than would be expected, from what is known about the force of attraction between molecules There is general agreement that one of the causes of this weakness is the ease with which crystal planes can slip along adjacent planes, so that crystalline substances slide apart instead of resisting a direct pull up to the limit of strength of the molecular adhesions

Whether surface cracks seriously diminish the strength is a question which receives much attention, but although at first sight there seems to be some evidence in favour of this view, it does not seem certain that the effects sometimes attributed to these cracks are not due to slip planes The plasticity of wet crystals of rocksalt remains an intriguing mystery, two papers on fatigue and hysteresis in metals leave one with a sense of the importance of incipient cracks and localities of slip, as well as of the great complication of the problem

Lennard-Jones and Miss Dent contribute another valuable paper on the macroscopic properties of crystals with a completely ionised lattice, calculating these from the electrostatic forces between the ions this type of work will surely become of increasing importance At present not much can be done except with the fully ionised lattices, where the interatomic forces are the simplest possible, but two short papers (Taylor, Rawlins) foreshadow avenues of future investigation These papers represent the limit to which we can now go in deducing the properties of matter in bulk from those of individual atoms Richards gives an abstract of his work on internal pressures, a conception which has the advantage of dealing just as readily with the effects of molecular motion as with the forces between molecules, but the disadvantage of being in all points decidedly remote from molecular theory

Other papers include a qualitative deduction of the relative strengths of the adhesions round organic molecules, from observations on surface films (Adam), observations on soldered surfaces (Crow), and on a change in dielectric constant on solidification (Errera) The discussion is not, of course, a comprehensive treatise, but deserves close attention, especially by metallurgists and engineers

(2) Dr Chatley's little volume contains notes on a variety of subjects, ranging from the internal structure of the atom to surface tension, viscosity, lubrication, etc It is scarcely thorough or accurate enough for the serious student, and seems unlikely to attract the general reader, on account of the amount of calculation introduced into the text

(3) Mr Hatschek deserves very hearty thanks for his excellent and readable survey of viscosity in liquids The book is a model of what a monograph should be the historical, mathematical, and experimental portions are thorough, a great mass of experimental results is admirably marshalled so as to show the bearings on other subjects, technical 'viscometers' have their failings succinctly described, and a comparison of their performance with that of instruments really measuring viscosity is given as far as possible If all writers of scientific books did their work so conscientiously as Mr Hatschek has here, students of all classes would have a much easier task than now faces them

(4) Mr Boswall's treatise deals with the complete, thick film of lubricant used, wherever possible, to separate the moving parts of machinery It contains a full mathematical treatment of the hydrodynamics of films of lubricant, with very detailed applications to many types of bearings, including journal bearings and the new thrust bearings with tilting sectors the effects of the motions of the metal parts are fully considered The chemical properties of lubricants, although important in determining the adhesion of the oil films to the metal surfaces, and hence in making it easy or difficult to maintain a complete film, receive scarcely any attention, but are evidently considered outside the author's province The book should be very useful to engineers with good mathematical equipment, engaged on the design of bearings N K ADAM

Non-Euclidean Geometry

(1) *Vorlesungen über nicht euklidische Geometrie* Von Felix Klein Für den Druck neu bearbeitet von W Rosemann (Die Grundlehren der mathematischen Wissenschaften in Einzeldarstellungen mit besonderer Berücksichtigung der Anwendungsgebiete, herausgegeben von R Courant, Band 26) Pp xii + 326 (Berlin Julius Springer, 1928) 18 gold marks

(2) *Leçons sur la géométrie des espaces de Riemann* Par Prof E Cartan (Cahiers scientifiques, publiés sous la direction de Gaston Julia, Fascicule 2) Pp vi + 273 (Paris Gauthier Villars et Cie, 1928) 60 francs

THE two books under notice together constitute an excellent introduction to non Euclidean geometry in all its aspects The lectures of F Klein now appear in print for the first time under the editorship of W Rosemann, though a lithographed edition was published so long as thirty six years ago The present edition has been considerably changed as the result of prolonged consultation between the present editor and the distinguished author shortly before the death of the latter.

M 1

In its present guise, Klein's book is divided into three parts, the first of which constitutes an excellent introduction to projective geometry in three chapters The first two of these, on fundamental notions of projective geometry and on forms of the second degree, are new, the third, on collineations or projective transformations, was already included in the lithographed edition The second part deals with projective metric in six chapters, the last three being concerned more particularly with non Euclidean geometry These two parts together constitute four-fifths of the book, but there is a short third part in which the relations between non Euclidean geometry and other branches of mathematics are considered very briefly, with references to Riemannian spaces and to the restricted theory of relativity The general treatment is elementary, mainly algebraical, with scarcely any reference to differential geometry, and is admirably clear and profusely illustrated by diagrams, designed to assist the appeal to intuition

(2) The second book, by E Cartan, the author of a well known book on integral invariants, is based on lectures delivered during 1925–26 at the University of Paris It deals with the geometry of Riemannian spaces almost entirely by the methods of tensor analysis and of differential geometry, and in this respect forms a welcome complement to Klein's more elementary book The treatment is based on the methods of Riemann and Christoffel, though the more recent work of Levi Cività and others is fully considered

The first five chapters are to a certain extent introductory, dealing with such topics as vector and tensor analysis, curvilinear co ordinates in Euclidean geometry, Riemann spaces which are locally Euclidean, Euclidean spaces tangent to and osculating Riemann spaces and geodesic curves and surfaces The results obtained are applied in the sixth chapter to non Euclidean spaces The seventh and eighth chapters deal with Riemannian and vectorial curvature, and the last is on normal co ordinates and their applications

This book is much more analytical than Klein's, but, considering the difficult nature of the subject matter, it is very clearly written and commendably free from misprints The two books in their several aspects can be highly recommended to those who wish to become acquainted with recent developments in general geometry and to fit themselves for an intelligent comprehension of the geometrical basis of the general theory of relativity

Biology for All

The Science of Life By H G Wells, Julian Huxley and G P Wells To be completed in about 30 fortnightly Parts Part 1 Pp 32 (London The Amalgamated Press, Ltd, 1929) 1*s* 3*d* each Part

A NEW educational venture of great attractiveness is "The Science of Life," an exposition of biology, by Mr H G Wells, Prof Julian Huxley, and Mr G P Wells, a young physiologist, son of the senior author The work aims at doing for biological science what Mr H G Wells did for history in his famous "Outline," giving to the unlearned a vivid presentation of the essential data It is to try to be "clear, complete, and correct", and if the triumvirate cannot do this, who can? There is wisdom in having three authors (tres faciunt collegium), for there is always the possibility of a majority when opinions differ

We cannot read Part 1 of this serial without envying those who are coming to biology in these days, for the presentation is so picturesque and gripping Academic formalities have been thrown off without jettisoning accuracy, and everything is discussed in its bearing on everyday life The increased availability of science promises well for the future, for it is one of the most hopeful lines of human progress that we should become more and more able to utilise our heritage of well established knowledge

If we were asked what every young student should know when beginning his voyage of life after schooldays, we should answer—(1) the most significant steps in the history of the human race, (2) how to find his way about in the world of Nature, and (3) the laws of health and happiness We are not thinking at present of brain stretching disciplines like mathematics, or of character forming influences like poesy, but of sheer knowledge We can see that this "Science of Life" is going to help powerfully towards an understanding of animate Nature on one hand, and towards an understanding of the conditions of health and happiness on the other We wish it the success it deserves

The present part begins with the nature of life, a difficult problem to start with But it is treated very concretely and with an interesting historical background In any event the reader feels that if this is biology, he wishes some more Then the story turns to the everyday life of the body—in mouse and in man, and when this can be made vividly interesting, as here, we cannot have too much of it It is tragic to think of the vast

number of young people who leave school without any understanding of their bodily functions Such ignorance may have been bliss, though we doubt it, long ago, when all the ways of living were more natural, but to day it often means disaster We do not wish to suggest that the new book is particularly designed for young people—though they will welcome it—for it appeals to all who wish more science for more life In spite of all the expositors, it has to be confessed that a large proportion of the population remain in the Dark Ages as regards the working of their bodies

There are very effective and interesting illustrations, and the frontispiece shows a crowd of skeletons receding into the distance before the light of microscopy and biochemistry This we take to mean that necrology will be recessive and biology dominant throughout this book We trust that this will be so, but it has been our sad experience that the skeleton shows great persistence in its efforts to sneak back to the feast But all success to the triumvirate !

Our Bookshelf

British Chemicals, their Manufacturers and Uses being the Official Directory of the Association of British Chemical Manufacturers (Incorporated), containing a Full List of Members, with a Classified List of British Chemicals and a Note of their Applications Pp 330 (London Ernest Benn, Ltd , 1929) 10*s* 6*d* net

Salesmanship, so far as it is regarded as a scientific art—one had almost been betrayed into writing ' artful science '—has of late been the subject of some discussion and doubtless of some new resolves To judge by the general agreement with which certain observations recently made by H R H the Prince of Wales have been received, salesmanship in the modern sense of the term is not one of the strong points of British commercial organisation, at least so far as markets overseas are concerned All the more credit and publicity should be given to the foresight of those manufacturers who have gone some way towards anticipating at least one criticism—that deploring the lack of adequate presentation to possible purchasers of information in their own languages Replacing the 1927 issue, a new edition of " British Chemicals, their Manufacturers and Uses," the official directory of the Association of British Chemical Manufacturers, Incorporated, has now been published The new volume, fully revised, is modelled on the lines of the last edition, and it is intended to bring the book up to date every second year The Association is not itself a trading concern, but exists to promote and facilitate business relations between manufacturing and chemical firms and purchasers all over the world, and to encourage legitimate international trade conditions

The directory—a sturdily bound volume—is printed (in part sectionally, in part collaterally) in English, French, Spanish, Italian, Portuguese, and German , even the title page and introductory information appear in sextuplicate A directory of members of the " A B C M " and of affiliated associations is followed by a classified list of products, their uses, and the names of British manufacturers There is also a list of proprietary and trade names, the corresponding chemical synonyms or descriptions, and again the names of manufacturers There is, for example, no longer any need for perplexity regarding the nature or origin of abralac, acrosyl, adalin, or even of westrosol, yarnite, or zinc formosul Since the list of products is arranged in the alphabetical order of the English names, supplementary indexes in the other languages are provided The reviewer understands that although the volume is offered for public sale by the publishers, Messrs Ernest Benn, Ltd , the Association, the address of which is 166 Piccadilly, London, W 1, will nevertheless send a complimentary copy to any applicant who is actually concerned with work in pure or applied chemistry A A E

The Origins and the Growth of Chemical Science By J E Marsh Pp x + 161 + 10 plates (London John Murray, 1929) 5*s* net

Mr Marsh endeavours to show that chemistry has advanced, not through haphazard experiments and discoveries, but by a gradual development of accepted knowledge with the application of logical reasoning to explain established facts Thus, when Boyle found that mercury calx was re converted into the metal by heating alone, he was unable to explain the fact When the phenomenon was rediscovered a century later, science was ready for it Joseph Black had observed the fixation of a gas in carbonates and the genius of Lavoisier enabled him to establish and explain the fixation of another gas in calxes

In tracing the growth of chemical science, the author has discarded the practice initiated by Kopp of dividing the development into epochs, since he considers this allows the dominant views of the time to obscure many important tendencies He instances the phlogiston epoch, which Kopp dates from 1650 to 1775 The discoveries of Boyle and Black are thus made to fall within the same period, yet Boyle never heard of the theory, which was only promulgated in 1702 and, moreover, did not come into prominence until Lavoisier began to attack it in 1775

The book opens with an account of the early views on the phenomena associated with fire, a study of which led to many important observations This section, and those dealing with alchemy, the fixation of gases, and some of the later ones cursorily tracing the theories of structure, are well written In dealing with the philosopher's stone, Mr Marsh has, however, accepted the doubtful view that Talbot and Kelley are the same person

The section devoted to the discovery of the elements, which follows an account of Mendeléeff's periodic law and other generalisations under the title "Atoms and Ions," is perhaps not so useful as it might have been Here the references to the literature are quoted in a confusing manner Frequently the year, volume, or page (sometimes two) are omitted, and German titles are occasionally misspelt (*e g* Poggendorff's *Annalen der Physik*), and the reference (p 144) for 'the octet theory of valency' (Abegg *Zelt An Org Chem*, **39**, 330) will irritate those who desire to consult the original

In spite of this minor defect, the book presents a useful survey of the origins and development of chemical science J G F Druce

Introduction à l'étude de la physique théorique Par Prof René Fortrat Fascicule 6 *Mécanique statistique* Pp ii + 100 (Paris J Hermann, 1927) 10 francs

It is always rather difficult to estimate the value of one detached section of a larger work, for the scale and plan of the whole work can only be guessed This difficulty is particularly noticeable in attempting to review on its own merits this section of Prof Fortrat's work entitled "Statistical Mechanics"

To write a successful fairly elementary account of statistical mechanics in a hundred small pages is a task requiring great delicacy of judgment in selecting material On such questions of taste one need not ask for complete agreement, but the reviewer is forced to admit that he finds the author's judgment poor In the first place, the last forty pages of the book are devoted to two chapters on the older quantum theory of the atom, too slight to be of much value in themselves and entirely irrelevant to the professed subject matter They contain, incidentally, statements about the discrepancy between the magnetons of Bohr and of Weiss which might lead an unwary reader to suppose, contrary to the facts, that there is a real difficulty and that the Weiss magnetism is still of some theoretical importance

The remaining relevant sixty pages are rather good and rather unusual The subject is treated from the conventional probability point of view, but the ideas and computations of the theory of probability are presented in detail and well illustrated in a way which owes much to Langevin The applications of the theory have the pleasing and unusual feature of being mainly to magnetic phenomena There are good short accounts of Langevin's theory of paramagnetism and Weiss's theory of ferromagnetism If the rest of the book were of the same standard, it could be warmly praised R H F

The Mechanics of Rowing By W B Coventry Pp viii + 70 (London E and F N Spon, Ltd, New York Spon and Chamberlain, 1928) 4s 6d net

This is an interesting addition to the literature of rowing, and the work is soundly based on Newtonian mechanics The terms used are carefully explained, as is also the fundamental problem of connecting the equation of motion of the blade of the oar with the equation of motion of the boat The variable nature of the effective propelling force is dealt with by the introduction of a constant 'mean effort' operating from the catch to the finish of a stroke

In the application of the theory to definite examples, it is rightly recognised that, in the last resort, the solution depends on the 'personal equation' of the oarsman Discussion of such subjects as the length of the stroke, the sliding seat, the weight of the crew and of the coxswain, indicates the practical interest in the racing 'eight' round which the book centres The effect of the density of the water is dealt with, and perhaps reference might have been made to Thomson's theorem and its application to the hydrodynamical problem of rowing a boat in shallow or deep water The book concludes with emphasis on stamina and quickness as more valuable assets than big muscles H D A

Eutychus or the Future of the Pulpit By Winifred Holtby (To day and To morrow Series) Pp 142 (London Kegan Paul and Co, Ltd, New York E P Dutton and Co, 1928) 2s 6d net

Miss Holtby's clever book, which reminds one occasionally of Oscar Wilde, is well worth reading Students of science are perhaps not much interested in the future of the pulpit, and may agree with Anthony, the young intellectual, that "the pulpit has no future because religion has no future" But the book does, among other things, present an accurate picture of a certain type of vulgar sentimentality which pervades large sections of a modern community Men of science for the most part are quite unaware of its existence, since their work only brings them into touch with intelligent people In this dialogue, Eutychus is the exponent of popular religious notions, the devotee of what we may call 'Abide with me' religion, with its cinema mentality and vulgar emotionalism Moreover, Eutychus feels that he holds all the cards "Whatever the sermon is to be you may be sure that it depends upon just how much I and my friends can stand you've got to pay attention to what we stand for," says he No wonder that Fénelon, the exponent of Catholic orthodoxy in this dialogue, sums up the situation by saying, "It is the influence of Eutychus which alarms me most" J C H

A First Book of Experimental Science By W A Whitton (First Books of Science Series) Revised and enlarged edition Pp vii + 194 (London Macmillan and Co, Ltd, 1928) 2s 6d

A welcome will be given to this enlarged edition of a school book which has already proved its worth As to standard, it suits candidates for the junior local examinations, and as to scope, it deals with hydrostatics, mechanics, heat, and a little chemistry

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

The Equivalent Heights of the Atmospheric Ionised Regions in England and America

IT was recorded in NATURE of Sept 3, 1927, that, in experiments carried out for the Radio Research Board of the Department of Scientific and Industrial Research, evidence had been obtained of the existence of at least two ionised regions in the upper atmosphere This evidence was derived, in the first instance, from observations made at night using wireless waves of medium length as the atmospheric exploring agency, but, more recently, the use of short waves has made it possible to carry out similar experiments during the daylight hours The results of these experiments confirm the earlier conclusion as to the existence of the two ionised regions while the use of short waves, as was anticipated, markedly lengthens the period during the twenty four hours when the lower region is penetrable and the upper region accessible Using a wave length of just under 100 metres, it is found that even about mid day the lower region is penetrable on some days On other days it is found that due to the inhomogeneity of the lower region, waves of this length are reflected by it one moment and a short time later got through This is illustrated by a typical series of observations made at King's College, London, on Jan 13, 1929, using 99 8 metre waves emitted by the National Physical Laboratory transmitter at Teddington, for which the following equivalent heights (km) of reflection were recorded at 10 minute intervals between 1000 and 1400 G M T 229 229, 236, 244, 217, 229, 229, 230, 204, 196, 229, 100, 99, 93, 98, 99, 96, 98, 232, 99 (and 220), 99, 229, 229, 99

It will be seen that these heights fall into two definite series, of mean values 226 km and 98 km

Now measurements of the equivalent height of the ionised layer have also been made in America, and it is of interest to compare the English and American results under similar conditions For example, Breit, Tuve, and Dahl (*Proc Inst Rad Eng*, vol 16, 9, p 1236, 1928), employing their elegant group retardation method, have recorded that, at Washington, using 75 metre waves, they obtained evidence of multiple reflections in that effective heights in the ratio 1 2 4 had been measured The actual heights recorded were 105 km , 225 km , and 450 km

Now we may identify the value of 105 km in America as corresponding to the 98 km (lower region) in England But in considering whether the remaining rays are multiply reflected rays from this region or not, we may note that, in terms of such an explanation, the triply reflected ray is missing and that the photographs show that the doubly reflected ray is often of greater intensity than the singly reflected ray Both of these difficulties disappear if we adopt the double layer hypothesis for the American results as well as for the English observations. According to this explanation, singly reflected rays were obtained at Washington from regions at heights of 105 km and 225 km , and a doubly reflected ray was also obtained from the upper region A close correspondence with the English mean values of 98 km and 226 km is thus obtained

Solutions and Heat Engines

IT is not usual for an author to complain of a review of his book, but I confess that the theory of osmotic pressure put forward (in place of an account of my own reasoning) by the reviewer, in NATURE of Feb 16, of my book "Gases and Liquids," almost took my breath away As the reviewer's reply, in NATURE of Mar 9, to Prof Armstrong's criticisms of this theory seems to me totally inadequate, perhaps I may be allowed space for some remarks

The reviewer says that in a solution "the effect of the bombardment [by solute molecules] is to tend to expand the volume of the solution, and that therefore if water can flow in through a membrane it will do so" This theory implies that a net positive expansion pressure acting from within on the walls of the containing vessel is produced owing to the presence of the solute, and at the same time a net negative pressure causing water to pass in Any less coherent theory I am unable to conceive In a solution, no appreciable pressure towards either the outside or inside of the solution exists until the semi permeable partition is brought into contact on the outside with pure solvent or a solution not isotonic with the solution in the osmometer There is no pressure because, though the solute molecules exercise pressure, the pressure of the solvent is correspondingly diminished, just as, with gas at constant volume and pressure, there is no change of pressure when we substitute an equal volume of another gas at the same pressure for part of the original gas The osmotic' pressure which develops in an osmometer is quite evidently due to the fact that the more concentrated molecules of the pure solvent diffuse through the semi permeable membrane faster, until the full osmotic pressure is developed, than the diluted solvent molecules in the solution It is thus to the solvent, and not to the solute molecules, that the pressure is due, as Prof Armstrong has pointed out

In my book I have developed this theory quantitatively, and shown, as I think, that it gives the actual experimental figures for depression of freezing point elevation of boiling point, and osmotic pressure, though not what van t Hoff wrongly thought were the figures While I am sorry that the review has given no account of the reasoning in the book, I must not complain but I think I am justified in joining my protest to that of Prof Armstrong against what seems to us and many others the incoherent theory put forward by the reviewer

I have tried in my book to be fair to the memories of van t Hoff and Carnot, both of whom were men of outstanding genius But where they were in error they were just in error, like other mortals

J S HALDANE

DR HALDANE considers my statement of van 't Hoff s theory (it is not mine) as incoherent I cannot do better than quote, as an alternative statement, from the account of osmotic pressure in the book under review (p 109) "Let us imagine pure hydrogen and pure nitrogen at ordinary atmospheric pressure and contained in two equal gas tight chambers separated from one another by a rigid septum permeable to the hydrogen but completely impermeable to the nitrogen The hydrogen contained in chamber 1 will immediately begin to diffuse into the nitrogen in chamber 2, and will continue to do so until the pressure of the hydrogen is the same in the two chambers If the pressure in the first chamber is kept constant, by reducing its volume or letting in hydrogen as required, the pressure in the second chamber will be two atmospheres"

No better illustration than this can be given of osmotic pressure, which in this case is one atmosphere (*i e* the difference of pressure between the two sides of a semi permeable membrane when equilibrium exists) This extra pressure is due entirely to the fact that on both sides there is now hydrogen at one atmosphere pressure, but in No 2 there is nitrogen as well Thus there is the extra bombardment inside, and in this simple case (assuming the gases perfect), it is calculable exactly from the expression $pV=nRT$ The nitrogen bombards also the semi permeable membrane, but this does not prevent the hydrogen from coming in (though with actual molecules, presenting a broad front for attack, it will slow down its *rate* of coming in) It maintains a space extended to receive the hydrogen molecules If the vessel can stretch, it will do so in consequence of this extra bombardment, and fresh hydrogen will come in to equalise the pressure of the hydrogen once more

Now, whether we are dealing with gases at low or at high pressures, this kinetic pressure is the same at any given temperature Perrin's experiments make it certain that it is so even for a condensed gas (*i e* a liquid) Serious complications then come in, however, which make exact calculations impossible, but the kinetic pressure is there all the time, and for solutions so dilute that the solute molecules are out of each other's way most of the time, it is found from osmotic measurements to be practically that which a gas would exert if of the same molecular concentration and occupying the same space alone It is no use, therefore, trying to drag in other causes to explain the existence of osmotic pressure, and in any case it is inexcusable to neglect the kinetic effect

Dr Haldane attempts to attribute the *whole* phenomenon to certain volume relations depending upon the replacement of little molecules of solvent by big molecules of solute (thus ignoring the forces which govern the affair), the van 't Hoff school treats these simply as complications, and recognises at the same time that questions depending upon the sizes of molecules and of the attracting forces between them are problems of such extraordinary difficulty that the accurate allowance for their influence has not yet been effected In dilute solutions their effect is certainly very small

Dr Haldane is not at all clear on this part of his subject, and since his whole theory depends upon the precise assumptions made, I thought it best in my review to be content with indicating that the theory was a superfluity, a *vera causa* having already been recognised and successfully developed Since, however, he evidently desires me to do more, I must mention that on p 25, where he introduces the volume relations which are the basis of his 'theory,' the results deduced are algebraically wrong So that, even assuming that the fairly simple gas law which he takes is good enough, the conclusions that he draws are unfortunately incorrect I sympathise with him for, also unfortunately, I am personally acquainted by experience with many of the pit falls which abound

THE REVIEWER

Perturbations in the Band Spectrum of Helium

RECENTLY Kronig put forward a theory of perturbations in band spectra (*Zeit f Phys*, **50**, 347, 1928) He found that if two molecular terms with the same j, which have besides to fulfil certain other conditions, come close together, their mutual influence has the effect that they seem to repel each other Hitherto no band spectrum has been sufficiently known to permit of testing Kronig's predictions

In the helium band spectrum a great number of electronic terms is known, and it is therefore especially well suited for a test of the theory of the perturbations In Fig 1 the empirical differences between the $4s(j)$ and $4z(j)$ states are represented as a function of j We see that for $j=17$ the corresponding energy levels come very close together, and as the two levels fulfil

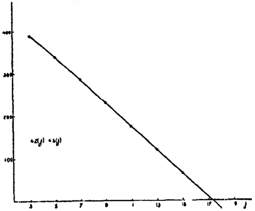

FIG 1

all the requirements of Kronig's theory, we must expect that they will be shifted from their normal positions Fig 2 shows how the empirical terms are distributed in the vicinity of the critical point The dotted lines give the positions which the terms would have if there was no perturbation The actual term values derived from the analysis of the bands $2p-4s$ and $2p-4z$ show just the expected deviations (The absolute value of the perturbations has been exaggerated in the figure in order to make it better visible) The exact position of the terms with $j=19$ and higher is not yet quite sure, as there is a choice of several unclassified lines in that region It is certain, however, that although the intensity of the preceding lines is large enough, so that we can also expect with appreciable intensity the lines having the terms $4s(17)$ and $4z(17)$, etc, as initial levels, they are not present in the extrapolated positions Therefore it seems certain that we have indeed here a mutual interaction between the corresponding s and z terms Similar perturbations seem to exist for the five quantum terms, but as the situation is not so unambiguous as in the case mentioned above, their communication is reserved for a later occasion In the case of three quantum terms, a similar approach of terms with the same j does not take place, and accordingly perturbations have not been found

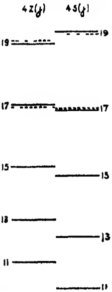

FIG 2

The perturbation of the $4p(9)$ term first found by Curtis in the Q branch of the band $\lambda 367$ mμ, seems to be of a somewhat different nature A term which might interact with the $4p$ term so as to give perturbations is not yet known It does not seem impossible that the initial term of the band $\lambda 535$ mμ analysed by Fujioka (*Zeit f Phys*, **51**, p 657, 1928), which shows a perturbation for the same value of j, is

the term which is responsible for them The perturbation of the $4p(9)$ term shows a doubling of the corresponding Q line into two components with unequal intensity This might be explained in the following way The spectrum of the helium molecule must consist of single and triple electronic terms But as the interaction of the electronic spin with the rest of the molecule is very small, the triplets are not resolved and thus have the appearance of single levels It seems possible that in the case of a perturbation the interaction with the spin gets an abnormally large value, so that the corresponding term is split up We must imagine, then, that the more intense component of the corresponding line is, as in the case of the atomic lines of helium, an unresolved doublet

Full particulars of these and other properties of the terms of the helium molecule will be given elsewhere

Cosmic Rays

IN an earlier communication [NATURE, Feb 16, p 241] it was stated that an examination had been made of the results of experiments on cosmic rays The experiments referred to were those of Millikan and his colleagues In a recent paper (*Physical Review*, October 1928), Millikan and Cameron divide the rays into four bands with absorption coefficients per metre of water, 0 30, 0 08, 0 04, and 0 02 respectively There is very little, if any, evidence for the existence of the last band, and I find that their results are fitted just as well by the division of the rays into two bands only, with absorption coefficients 0 30 and 0 051 respectively, rays of type A and type B, say The experiments of Millikan and Otis and others show that there is a third type of radiation present, type C, say Rays of this type are of local origin and consist, in part at least, of β rays with an energy of the order of 100,000,000 electron volts

Rays of type B are probably γ rays If so, according to the Klein–Nishina formula, which, for large values of $\alpha = h\nu/mc^2$ reduces to

$$\sigma/\rho = \frac{4\ 17}{\alpha}(1 + 2 \log 2\alpha) \qquad \text{per metre of water}$$

α for these rays equals 173, corresponding to an energy of 88,000,000 electron volts

Rays of type C are doubtless γ rays, with a value of α equal to 1330 and an energy of 675,000,000 electron volts

The energy presumably released when an oxygen nucleus is formed in a single step from protons and electrons is 116,000,000 electron volts, and that when a proton is destroyed 940,000,000 electron volts I believe that the formula used gives values of α which are too small, so that rays of type B may correspond to the radiation emitted when an oxygen nucleus is formed in a single step and those of type C to that when a proton is destroyed Incidentally, it has been tacitly assumed that rays of both types exert no appreciable action on hydrogen and oxygen nuclei The evidence that rays of either type have any effect on atomic nuclei is not conclusive

An analysis of the results of experiments showing the variation of intensity of cosmic rays with depth below the surface of the atmosphere affords, then, no evidence of rays corresponding to the formation of helium nuclei from protons and electrons This renders it difficult to accept the attractive hypothesis of Millikan and Cameron that atom building is taking place in outer space, following the transformation of radiation into protons and electrons Another difficulty that occurs is this If all the energy in starlight is so transformed, less than eight tenths of one per cent of it can be re radiated as cosmic rays As the radiation from the sun apparently has no effect on the intensity of the rays, this amount seems too small to account for the large intensity of cosmic rays, estimated by Millikan and Cameron to be about one-tenth that of starlight

Rays of type C are not easy to classify Their intensity in air is approximately proportional to that of the rays of type B, although it is difficult to estimate the exact value of either They are not produced in water or in lead, and are therefore not recoil electrons Many methods of explaining their origin have been tried, one being that they are photoelectrons ejected from the nuclei of atoms such as nitrogen, but this explanation is not altogether satisfactory

We have assumed that rays of type A and C are cosmic in origin, the greater part of the evidence favouring this view, but one experiment carried out by Millikan and Otis indicates that a part at least of these rays may be of terrestrial origin and also that rays of type C may be more penetrating than is usually assumed They measured the ionisation in an electroscope before and after a snowstorm When the electroscope was shielded by 4 8 cm of lead the ionisation per c c per sec (corrected for natural leak) dropped from 4 9 to 3 6 If this result is not due to experimental error, it would appear that something had occurred in the atmosphere to diminish the intensity of the rays of one or more types

A more complete discussion of the questions raised above will be given later In searching for an explanation of the results, equations of the following type have been used, namely

$$14\ 008x + 4\ 0022x + \alpha_k = 17\ 000x + 1\ 0078x + p_k + A_k + h\nu$$

This is an energy equation representing the ejection of a proton from a nitrogen nucleus by an α particle, the α particle being captured by the recoil atom forming an oxygen isotope of mass 17 (the number 17 being assumed) x represents the energy in electron volts radiated when unit mass is destroyed (the mass of an oxygen nucleus being taken as 16 units), α_k, p_k, A_k, and $h\nu$ representing the kinetic energies in electron volts of the α particle, ejected proton, recoil atom, and assumed radiation respectively

$$h\nu = 0\ 0024x + \alpha_k - p_k - A_k$$

As $x = 930{,}000{,}000$ electron volts and $p_k + A_k$ is less than α_k, $h\nu$ should be greater than 0 0024x, that is, than 2,230,000 electron volts

It should be possible to detect radiations of this type Similar equations have been written down for the other atoms from which protons can be ejected, but the results are somewhat indefinite, as we do not know the mass of the recoil atom

The Ice Age and General Drayson's Theories

I AM sure your able contributor H C P did not intentionally misrepresent Drayson in his article in NATURE of Dec 29, p 1002, but it would seem that some initial unfamiliarity with Drayson's writings, or possibly lack of sympathy with his claims, has led to misapprehension, and I would ask you to be so good as to permit me to direct attention to the more serious mistakes

(1) "Everywhere in the Draysonian literature nutation is simply ignored"—Nowhere, and at no time, did Drayson ignore nutation, in proof, see "Untrodden Ground in Astronomy and Geology," p 83, "Motion of the Fixed Stars," p 23, etc, though, in common with Sir John Herschel and all other astronomers, when tracing the path of the pole, he had, inevitably, to deal with the *mean* path The greatest amplitude of nutation, that is, the whole nodding movement across the *mean* path, in direction towards the centre of the circle traced by the pole, is only 18½ seconds of arc It would need to be 1167 (one thousand one hundred and sixty seven) times that amount to explain the 6 degrees remove of the precessional centre from the ecliptic pole which Drayson discovered on examination of the records for the previous fourteen hundred years

(2) "Further than this, the description, such as it is, is devoid of any dynamical basis"—Over and over again, in all his writings, for example in "Untrodden Ground," pp 256 259, Drayson directed attention to the existing terrestrial conditions that would appear to necessitate a precession different from that assigned to the earth by the mathematicians, a difference he demonstrated by actual experiment with the gyroscope It is not quite correct, therefore, to say that the movement he described is devoid of any dynamical basis While it would be out of place to question the calculations of the master mathematicians who have determined the precession dynamically, may it not be reasonable to suggest that the data on which their workings are based are necessarily in the nature of assumptions, difficult, if not impossible, to verify and liable to modification ?

May I add that, while it is not necessary to contend for every word that Drayson has written (and he himself was frank to own the limitations of his single handed research), the need all through has been for simple recognition of the fact that he was offering to science something well worth the trouble of bona fide examination and the need to day is as great as ever for co operation of friendly team work, in place of aloofness, to thresh out the question in all its bearings and harvest for science all that is of permanent value

T C Skinner

Reigate

The moderation of Lieut Col Skinner's letter, in marked contrast to the tone too often adopted by the advocates of Drayson's theory, entitles it to a reply, though without any hope of changing settled convictions The invitation to join in friendly co operation under the banners of Laplace, Poisson, and General Drayson is touching and deserves to be appreciated

Casual mention of a matter like nutation is quite consistent with ignoring it in practice Col Skinner denies that it has been ignored, and at the same moment seeks to justify that course on the plea that nutation is very small But the problem which Drayson approached was that of the motion of the earth about its centre, and in that problem dynamical astronomy has to deal with precession and nutation together From this point of view the relative magnitude of the latter is irrelevant As well might one leave out of sight the loops in a row of knitting on the ground that very fine needles were used

This failure to grasp the integrity of the problem in itself betrays the lack of any dynamical basis in the treatment of it Col Skinner refers to mistakes, and has had an opportunity of correcting them It will be observed that in the one case he has failed to indicate what part, if any, nutation plays in the Draysonian scheme, and in the other he has not suggested in what way, if any, the scheme derived support from dynamical reasoning of any kind Drayson may have alluded to nutation and toyed with gyroscopes (most people have spun tops in their time), but what remains as obscure as ever is what part these things played in a theory the purely geometrical and empirical character of which is as clear as day

An attitude of Athanasius *contra mundum* may be impressive, but the majority is not invariably wrong The work of the master mathematicians, so far from being sacrosanct, has received repeated and critical study The unfortunate thing is that Drayson and his followers have never shown the slightest inclination to come to close grips with it When they have undergone this arduous discipline, they will have formed a juster view of the situation H C P

Compressibility of Crystals and the Exponent of the Force of Repulsion between Atoms

It is recognised that a real crystal does not have a perfectly uniform structure, but that it consists of a large number of small perfect crystals with a system of submicroscopic cracks between them The average size of the perfect unit is, according to A Smekal (*Zeitschrift fur technische Physik*, p 535, 1926), about 10,000 molecules The presence of the submicroscopic cracks is made responsible for the tremendous difference between the experimentally determined values of tensile strength and those computed from theoretical considerations As is known, the latter are several hundred times larger

M Born ('Atomtheorie des festen Zustandes,' pp 734 735) calculates the exponents of the forces of repulsion between the ions in a crystal lattice from the compressibilities of the crystals In this way he arrives at the well known value 9 from which certain conclusions of importance are drawn as to the symmetry of electronic arrangements in the ions (resp atoms) The fundamental implicit assumption of all calculations of such a kind is that the coefficient of compressibility, as determined by the usual methods, is characteristic for the ideal crystalline space lattice

Are we justified in making this assumption? If the tensile strength of a crystal is reduced several hundred times due to its loose structure, should we not expect that the compressibility, as usually determined, is also a characteristic, not of the ideal perfect crystal, but of the real loose crystal ? It is easily seen that if the above mentioned structure of the real crystal should have any influence at all on its compressibility, the effect should be one of increasing the latter When subject to compression, the real, loose crystal may decrease in volume solely due to closer packing of the perfect units, that is, due to a decrease of the volume of the system of submicroscopical cracks The compressibility of the individual crystallites may be very small, even zero, and still the crystal as a whole may show a considerable reduction of volume under pressure

It is difficult to estimate how large such an effect may be But the following considerations may give some indications According to Siedentopf, the width of the submicroscopic cracks is of the order of 10^{-7} cm (W Rogowski, *Archiv fur Elektrotechnik*, vol 18, p 147, 1927) Assuming the crystallites to be cubical, we find that there are about 21 atoms along the edge of the cube If, furthermore, we

assume that the width of the crack given above represents the average spacing between the adjacent crystallites, we find that the total volume of the cracks is of the same order of magnitude as the volume actually occupied by the perfect crystallites This is certainly much too high an estimate But it now becomes not improbable to assume that the total volume of the cracks equals within a few per cent the volume of crystallites The compressibilities being of the order of 10^{-6} cm ^{2}/kgm , we see that even at pressures of about 10,000 atmospheres the relative change of volume is only a few per cent Hence, it is not impossible that practically the whole change of the volume is due to the decrease of the size of the cracks

Hence we see that the measured compressibilities may be considerably larger than those which would be found if we dealt with a perfect crystal But this means that the exponents of the forces of repulsion between the ions are considerably higher than 9 If this should be confirmed, it would necessitate also a revision of some of the conclusions drawn from previous data It is perhaps worth noting that J E Jones (*Proc Roy Soc*, A, vol 106, pp 441, 463, 1924, and vol 107, p 157, 1925) finds for some gases considerably higher exponents from different considerations

Since the system of cracks in a real crystal is of prime importance also for a great number of other properties, such as conductivity of dielectrics, optical phenomena (Smekal, *l c*), and electrical break down strength (Rogowski, *l c*), it may perhaps be possible to investigate this question by the study of the above mentioned properties under high pressures

The Beta-Hormone

THE œstrous cycle is but one phase, and the less important phase, of the whole sexual cycle There are *no* mammals in which the reproductive phase of the cycle (pseudo pregnancy) does not also occur —either regularly or under given conditions But there are *some* (the primates) in which no œstrous phase appears, since the whole cycle consists of a pseudo pregnancy Pseudo pregnancy depends upon a hormonic function of the ovary, and is entirely independent of the presence of ova, fertilised or unfertilised, mature or immature (Wiesner, 1927) It becomes necessary, therefore, to decide whether pseudo pregnancy is caused by the same hormone or hormones as that which invokes the œstrous cycle

Alpha hormone (œstrin—the cornifying factor) in particular must be tested But Wiesner has shown that alpha does not produce the typical changes of pseudo pregnancy Moreover, an already existing pseudo pregnancy can be interrupted by injections of alpha

In an attempt to explain the mechanism of the sexual cycle, the assumption was made that there existed a second ovarian hormone which was required to act in two ways (*a*) to prevent alpha causing œstrus (in animals where alpha occurs during the second phase—be it pseudo pregnancy or pregnancy), (*b*) to produce the typical changes of pseudo pregnancy which cannot be produced by alpha

Recent work done by Wiesner in 1927–28 and by ourselves aimed at the isolation of this hormone or the factors of which it consists Now we have found that the corpus luteum contains a substance which can be extracted and causes at least some of the effects ascribed to this hypothetical beta hormone

The method of extraction was one of those which were used in the preparation of rho one (ρ_1)—that particular 'pituitary' hormone which causes œstrus and ovulation in the diphasic animal (Wiesner and Crew, 1928) The simplest method is that of shaking an aqueous suspension of finely divided substance of corpora lutea (cattle) after addition of sulpho salicylic acid (conc about 15 per cent) A precipitate forms, and filtration leaves a large part of the beta in the liquid, the evaporation of this extract at 56° and the removal of the sulpho salicylic acid from the residue by means of alcohol leaves a water soluble substance the injection of which can produce effects required of beta by the working hypothesis For it prevents the atrophy of the uterus in ovariotomised mature mice, a phenomenon appearing normally in all castrated animals, the muscular layers of the uterus of the experimental animals showed full development The epithelial cells are increased in number and size high epithelial activity prevails The uterus never appears to be dilated by fluid (as it is after injections of alpha) The vaginal epithelium is *not cornified*, but forms *a layer of high mucous cells*—as in pregnancy or pseudo pregnancy

The effects caused by this substance, the beta factor of the ovarian hormone, permits one to conclude that it is one, if not the factor, which is responsible for the second phase of the sexual cycle (pseudo pregnancy) in diphasic animals and for its equivalent (premenstruum) in monophasic animals

Further purification of the extracts and a study of the effects of beta is the object of experiments now in progress, the formation of that particular vaginal epithelium which can be recognised in a small excised piece of the vaginal wall and is characteristic for the second phase is used as the test for the presence of this ovarian hormone, which is the second, but most probably not the last one to be extracted and described

Practical Television and its Problems

THOUGH I see that it is largely taken from a foreword written by so high an authority as Sir Ambrose Fleming, I should like to put on record my strong dissent from a sentence in the review of A Dinsdale's book "Television," in the supplement to NATURE for Mar 9 The statement that I object to is "The great obstacles to radio television to great distances at present are the disturbances caused by fading Morse signals, atmospherics, and all the other causes which mutilate the broadcasting of speech and music"

On the contrary as a matter of fact, if the difficulties occasioned by all these troubles were entirely eliminated, there would remain two fundamental, and, so far as present methods are concerned, insuperable difficulties against obtaining really successful practical radio television

The first, which applies to all television, either by radio or by wire over distances either long or short, is, that with present mechanical methods it is only possible to produce transmitting or receiving apparatus with which the pictures can be divided into numbers of units which, for real success, would have to be multiplied at least by hundreds, if not by thousands

The second difficulty applies only to television by

radio and not by wire, but applies obviously to broadcasting, and consists in the fact that where television is made by radio, such broad bands of frequencies must be used in order to get the necessary details to form really successful images, that these bands must cause unbearable interference with all other wireless systems in the neighbourhood

I may add that I have received both a letter, dated Mar 1, and a copy of an article in the *Elektrotechnische Zeitschrift* for Nov 29 last, from Prof Arthur Korn, of Charlottenburg, the well known pioneer in the transmission of pictures by telegraph, that fully bears out these views of mine He says in his letter, "In reality, I think that all the present trials of television are without great practical value, and only when it will be possible to receive many hundreds of thousands of elements per second practical television will begin"

A A. CAMPBELL SWINTON

MR CAMPBELL SWINTON loses few opportunities of attacking mechanical methods of television We have seen what we and many experts, including Sir Ambrose Fleming, consider excellent pictures transmitted by mechanical television It is somewhat late in the day to point out difficulties in the way to experts As Mr Campbell Swinton has quoted Prof Korn, we may be allowed to quote the following extract from a letter dated Feb 19, by Commandant Brenot, Chief Engineer of Radio Paris, one of General Ferrié's most brilliant pupils "What Mr Baird has done is far ahead of what the most optimistic spirits could have dared thinking only a year ago at the International Wireless Conference held in Washington"

Six or seven stations in America are already broadcasting television pictures by various methods with a somewhat limited amount of success Experimental transmissions on the Baird system will shortly be tried in various continental countries The matter is being considered at present by the Post Office officials in Great Britain and we are quite content to leave the question of broadcasting television in their hands, as we know that they are competent and quite unbiased

THE REVIEWER

Magnetic Storm of Feb 27-28

ON Feb 27-28 occurred one of the greatest magnetic storms recorded at this Observatory in the present solar cycle The range in declination (100′) has been exceeded once only, on Oct 15, 1926 (>164′), in the cycle, and that in horizontal force (530 γ) has been exceeded on three occasions only, namely, on July 8, 1928 (>600 γ), Oct 15, 1926 (>717 γ), and April 14-15, 1926 (585 γ) In both the recent storm and that of last July the minimum of H F was beyond the limits of registration, so that it is not possible to give the exact value of the range

The recent storm was not marked by a 'sudden commencement,' but was preceded by slight and moderate disturbances respectively at about the same hours on the two previous days The duration of the storm was approximately from 15 h 30 m on Feb 27 to 4 h on Feb 28, but the more violent phase was confined to the interval between 18 h 30 m on Feb 27 and 1 h 30 m on Feb 28 The character of the record strongly suggests that the violent phase of the disturbance was due either to a different cause from that responsible for the more moderate disturbances at the beginning and end of the storm, or to a marked discontinuity in the conditions under which a common cause operated This is especially observable in the declination record, in which all the maxima and minima of the violent phase are sharply pointed, whereas in the initial and final stages they tend to be rounded Further, the beginning and end of the central phase are very sharply marked, especially the end, which is as abrupt as if it had been brought about by the opening of a switch on an electric circuit

It is worthy of note that the most violent movement of the storm was centred at about 20 h on Feb 27, at which time, according to reports in the Press, telegraphic services were seriously disorganised Between 21 h 42m and 21 h 57 m there was a rise of 72′ in declination, followed by a fall of 80′ between 21 h 57 m and 22 h 2 m, whilst between 21 h 53 m and 22 h 8 m there was a rapid fall and rise in H F of over 370 γ, the trace being off the sheet from 21 h 58 m to 22 h

There were a few insignificant groups of spots near the central area of the solar surface, but nothing which would lead one to anticipate any notable magnetic disturbance, nor does the storm appear to be in sequence with any previous ones at about the 27 day interval It will, however, be interesting to see if it is followed by another at about Mar 26, and, if weather conditions are favourable, it would be well if observers would be on the look out for aurora at about that date

The Presence of Sulphur in the Gaseous Nebulæ

MANY of the strongest lines in the spectrum of the gaseous nebulæ have been explained (NATURE, **120**, p 473, 1927 *Astrophys J*, **67**, p 1, 1928) as forbidden transitions from low metastable states in oxygen and nitrogen The analysis of the S II spectrum by Ingram (*Phys Rev*, **32**, p 172, 1928), combined with the intercombination lines recently classified by L and E Bloch (*C R*, **188**, p 160, 1929), makes possible the prediction of the position of lines due to similar jumps in singly ionised sulphur as follows

Transition	λ Calculated	λ of Nebular Lines
$a^4S - a^2P_2$	4068 39	4068 62
$a^4S - a^2P_1$	4076 45	4076 22
$a^4S - a^2D_3$	6717 04	—
$a^4S - a^2D_2$	6731 30	6730 0

The last column of the table gives the wave length of lines found in the nebulæ The agreement in every case is within the error of the calculated wave lengths, which depend on frequencies of lines in the extreme ultra violet 4068 62 and 6730 0 were listed previously among the unclassified nebular lines (*loc cit*), while 4076 22 was provisionally assigned to O II, although its intensity was much stronger than the intensities of other O II lines would lead one to expect, and consequently the identification was indicated as being doubtful Judging by the behaviour of the homologous lines in O II, 6717 should be weaker than 6731, and consequently its failure to appear is not surprising

It may be noted that all of the elements thus far found in the nebulæ, namely, hydrogen, helium, carbon, nitrogen, oxygen, and sulphur, are gases or have stable compounds that are gases at low temperatures

British Oyster Fisheries

By Dr J H ORTON

THE present depleted state of the British—and indeed also of most European—oyster fisheries, with the resultant scarcity of marketable oysters, is the main cause of the current high price of this delicacy The high value of the native oyster (*O edulis*) especially, has attracted attention to the probable values of old and neglected former oyster fisheries, and to the possibility of beginning new fisheries in localities where such have not previously existed Any attempt at improvement of our inshore fisheries may be welcomed, and particularly when directed towards the culture of sedentary animals, which promise more definite economic returns for effort expended than most other fisheries A broad view of the problems in oyster-culture should, however, be regarded as a necessary preliminary to all new schemes, for, as Hoek insisted, " Oyster culture *is* a culture and not a manufacture "

One of the chief difficulties in oyster culture is the fluctuation in the supply of small stock—which is the equivalent of raw material in a manufacturing trade On many English oyster beds recurrent periods of relative scarcity of small stock occur not infrequently, while at longer intervals great scarcity of all kinds of stock may occur The cause of these minor and major fluctuations has been in the past undoubtedly mainly the failure of the crops of young oysters for successively few or many seasons In a good season many millions of young oysters may be obtained, in contrast with a very small fraction of this number in a bad season One good season in about five would ordinarily be sufficient to maintain a bed in a flourishing condition, provided an adequate breeding stock be always maintained

The present scarcity of oysters on English oyster beds is due to several causes, of which the failure of good crops of young oysters since 1921 is probably the predominant one Other factors of importance in this regard are (1) an unusual mortality in the Thames Estuary area in 1920, (2) over fishing, and (3) the possible occurrence of increased pollution in inshore waters with a resultant lethal effect on larval and young oysters These matters, along with a consideration of enemies, pests, local effects of unfavourable weather conditions, in addition to the purely economic factors, need to be considered in ventures upon oyster culture

The condition of British oyster fisheries is, however, intimately related to that existing in Holland and France, since these countries have in the past furnished a source of cheap young oysters for stocking British grounds In France, depletion of the beds (of *O edulis*) has occurred contemporaneously with and from causes the same as or similar to those operating on British beds Conditions in Holland have recently been more favourable, but have resulted here also in fluctuating periods of relative scarcity Thus at the present time stocks of small oysters are low throughout western Europe Table I, however, shows that stocks of all kinds of oysters, as judged from statistical returns, are relatively low over

TABLE I —THE WORLD'S OYSTER PRODUCTION FOR 1912–1926[1] (*according to statistics*)

Country	Chief Species Cultivated	Unit of Quantity Stated in	Total Value in Most Recent Year	Production in 1926	1925	1924	1922	1920	1918	1914	1912

[1] These statistics are given as stated in the various Government reports in the pre and post-War periods but as they relate to over lapping seasons are not all strictly comparable in the same year The figures for France relate only to the total output by oyster culture and those for England do not include the output from the Fal Estuary In each country the statistics are apparently comparable from year to year, and thus afford an index of the varying prosperity of the oyster industry in each region

[2] One bushel may contain any number of American oysters from 200 to 500 according to size

[3] One kwan = the weight of about 66 medium large English oysters

[4] Values for 1927 for respectively 1452 3 and 6·39 millions

[5] Value for 0 71 millions in 1927

[6] For the period 1911–1918

most parts of the world The true significance of these figures could be better estimated by comparison with a longer series, but nevertheless in themselves indicate the operation of some common factor or factors Of these factors, frequent failure of the young oyster crops and overfishing are probably the most important, with increasing pollution as a factor of least but possibly increasing importance

The occurrence of good crops of young oysters on English beds is closely correlated with warm summers, and on natural grounds there is little doubt that heavy falls of oyster spat are dependent directly or indirectly upon a more or less sustained temperature of the sea water at 60° to about 64° F or above In some seasons a good spatfall may be obtained, but even so, the yield of young oysters in the following spring may be slight, in other seasons, in spite of the demonstration of abundant larvæ in the waters over the beds, there may be little or a negligible spatfall It is advisable, therefore, to distinguish (a) the summer settlement of larvæ, as the spatfall, and (b) the product in the following spring, as the young oyster crop The best crops occur after long warm summers,[1] e g 1913, 1921, or from an early spatfall A complete scientific explanation of the factors concerned—which may be biological or purely biophysical—is still awaited, hence the need for prosecuting with vigour the investigations at Conway (referred to in NATURE, 123, 208) on the factors controlling spatfall and the survival of spat In the meantime, good crops of young oysters can only be expected on oyster beds either after long warm summers or when a warm period occurs in summer at about the time when a good proportion of the season's larvæ are ready to settle

Thus although researches on improved methods of spat-catching in the sea[2] may improve the oyster cultivator's probabilities of better crops, he is nevertheless dependent upon suitable weather, which is an unpredictable factor, for maintaining a succession of crops In this matter the steady production of millions of young oysters in artificial ponds at a cheap rate would immediately extend the possibility of oyster cultivation in Great Britain The English Fishery Department has already had considerable success in obtaining oyster crops in artificial tanks at Conway,[3] and it is suggested, could now attempt a *commercial* experiment on a grand scale, namely, prepare for and secure a crop of millions of young oysters, then, either sell the crop, or arrange to relay the product on existing oyster beds and cultivate them to a marketable size In the former case a demand sustained over a period of years would prove success, as would a satisfactory balance sheet in the latter In either case the Government might prove the value of its scheme empirically, before scientific assurance arrives

In the unusual mortality of oysters in the Thames Estuary in 1920, it was found impossible[4] to incriminate as the agent, trinitrotoluene, which had previously been dumped in this area in large quantities Nor was it possible to assign the mortality to any other lethal substance known to have been dumped in the sea in the post War epoch Thus the cause of the unusual mortality was necessarily left an open question it might have been due to unknown poisons, or to unrecognised parasitic disease The occurrence of heavy mortality in oysters at Taranto, Italy, in 1919, and on French beds, especially at Arcachon in 1920, renders it more likely that some parasitic organism was the common cause, though no suspicious parasitic form has yet been found As oysters are known to die from constitutional disorders brought on by extreme variations in external physical conditions, a determination of the cause of death in any given case is rarely possible The physiology of the oyster is thus extremely interesting from an academic as well as from an economic aspect For this reason—and others—it was strongly recommended[4] (1923) that a post graduate scholarship should be permanently founded for continuous researches on the physiology and biology of the oyster Such a scholarship was awarded to Dr C M Yonge for two years—and resulted in a valuable contribution to our knowledge of the physiology and anatomy of the oyster[5]—but has now unfortunately been allowed to lapse It may be again emphasised that the continuance of researches of this nature will add to our knowledge both of general biology and the special biology of the oyster in relation to culture

The effects of over fishing in the falling off of oyster production are, in the opinion of the writer, frequently underrated On a question of this kind, in which adequate scientific facts are not available, it is necessary to fall back on general principles One oyster can produce one million larvæ at a time, just as a codfish or a sea urchin may produce several million eggs, and it is often argued that quite a few individuals in a favourable season would be sufficient to produce a big stock of young The matter is important generally, and not merely confined to the oyster It is true that in extremely favourable circumstances a few individuals of one marine animal may produce a large population in the succeeding year or years, hence the view—especially held in oyster culture—that a stock may be reduced (over fished) to very small dimensions with impunity Fisheries in America, Australia, Scotland, and the German Bight have probably died out from acceptance of this doctrine It is, on the other hand, a generally accepted doctrine that the number of eggs produced per individual in a species is directly proportional to the probable rate of mortality before the attainment of full maturity, therefore when a stock is reduced to a few individuals, few young will survive, except in very favourable circumstances If such circumstances do not arise during the life of a surviving small stock, that stock will die out in that locality, whether it be oysters, sea urchins, sea-hares, ascidians, or other sedentary or semi sedentary forms, fishes—not being sedentary animals—fall in a different category

In order that a stock may be maintained in a certain locality, it would seem that a certain minimum number of individuals, which may be relatively large, is necessary It may reasonably be assumed that a fairly constant proportion of larvæ will

perish either from a multitude of enemies or unfavourable physical conditions, whether the total number be high or low; but if the number of larvæ be very low, there is a greater chance that all will perish. The conception that a minimum stock is necessary to maintain a species in a given locality thus arises. In the absence of any data on the problem, the economic limit of dredging has been suggested[1] as a practical minimum in the case of the oyster. The economic limit on the poorest English grounds works out at that state of the beds when about 50 to 100 adult oysters may be dredged per man per boat per day. With lower standards of living, or with very high prices, the economic limit may fall below this density. To-day the minimum stock necessary to ensure survival may therefore be estimated above rather than below the economic limit of dredging, as stated above, especially in localities where pollution is an increasing menace, since in the past the economic limit has not sufficed to ensure revival. In any event the careful cultivator will endeavour to maintain as large a stock as possible on the beds during the spawning season.

At the present day the spectre of pollution as a factor in diminishing or even preventing a spatfall, by destroying the larvæ, is probably in the background of the minds of most oyster producers. Oils are especially regarded with grave suspicion; but the small quantities of these substances relative to the volume of water with which they are mixed, and the small quantities of toxic ingredients in oils, renders it extremely doubtful that they alone can have any poisoning effect in *sea* water. There is, however, the broader aspect of general pollution to be considered. The additive effect of all the poisonous substances in the drains and sewers from industrial effluents especially—besides which tar and oils may be relatively unimportant—may be that of producing a very slightly unfavourable environment at first in a very small zone near the source of the effluent. This slightly unfavourable environment may be such as cannot be detected by any known method, and may result in forcing seawards the more delicate of the marine organisms. In many estuaries there can be no doubt, as Hautreaux (*Bull. Soc. de Géog. Comm. de Bordeaux*, II, 18, Bordeaux, 297, 455; 1895) long ago suggested, that the water oscillates up stream and down to a great extent as a result of the piston-like action of tidal waters outside;[6] the movements of shoals of estuarine crops of the jelly fish, *Aurelia*, for example, in the Hamoaze, Cornwall, and R. Blackwater, Essex, offer a simple means of observing this oscillation. Thus polluting substances or their products will tend to increase in such an oscillating body of water, especially between spring tides. Whether such a net pollution ever attains to lethal importance for the more delicate animals, such as oysters, in any particular locality is a legitimate subject for research, which, however, involves fundamental studies of the constitution of sea water. All coastal waters must be regarded as polluted—using the word in a general sense—in comparison with oceanic water, and the degrees of pollution of coast and estuarine waters may be more readily determined by comparison of their fundamental properties with the purer medium. The oyster cultivator will therefore welcome all schemes for the investigation of pollution and the maintenance of purity in estuarine waters.

Indeed, economic problems regarding oysters and oyster cultivation are so bound up with those in general biology that extensive co-ordinated researches prosecuted on the lines advocated in NATURE, **122**, p. 311, would serve both biological and economic aims, and might be the beginning of a new phase in British marine biological research.

On the economic side, it will be obvious from the account given above, and in NATURE, Feb. 9, that the oyster cultivator requires a long lease of the ground it is proposed to cultivate. Existing fishery rights must be acknowledged, and if necessary dredging rights of local fishermen may be accommodated by an allotment of shares in the new schemes.[7] In ventures in which the cultivator cannot expect to produce young oysters, that is, on purely fattening beds, State assistance cannot reasonably be expected. But where conditions are deemed favourable for the development of a new area for the production of young oysters, State aid in the early period of development may perhaps be reasonably asked for. In beginning a scheme for the production of oysters in a new locality, a fresh attempt is in fact being made to supply the raw material of an industry. In this respect oyster production is roughly analogous to beet production.

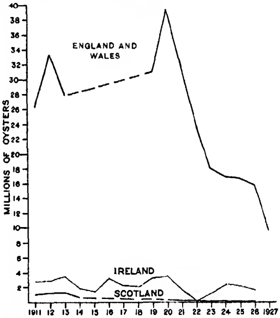

FIG. 1.—Output of oysters (mainly *O. edulis*) from oyster beds in the British Isles for the period 1911–27 (according to statistical returns). No records were kept in Great Britain during the European War.

New ventures which aim merely at fattening oysters will have to compete with well-established merchants, who on one hand are expert in their business, but on the other hand do not appear

to be able to meet the demand In new producing areas the essential characters of the grounds include

(1) Estuarine waters sufficiently enclosed—in a technical sense—to ensure the retention of the larvæ and spat in a maximum area under cultivation

(2) A local seasonal temperature range giving frequent probabilities of a maximum temperature in the bulk of the sea water of 64° F or more, and a minimum rarely below 34° F

(3) A large area of moderately clean ground, and moderately pure water which should not fluctuate greatly, nor fall much or often below 2 5 per cent, in saltness

(4) A sufficient stock of large oysters to supply probabilities of an increasing spatfall year by year

(5) A supply of cheap clean shell or other material for the annual sowing for spat

(6) Reasonable shelter from gales, if much sandy or fine gravelly ground occurs in the locality

(7) Immunity from gross sewage or industrial pollution now and in the fairly distant future

(8) Absence of an abnormal amount of enemies or pests

A review of these characters indicates that the southern regions of England and Ireland are most likely to yield new producing grounds, whilst a glance at Fig 1 suggests that potentialities for production in Ireland are undeveloped to a greater degree than in England

Vibration in Bridge Structures[1]

BRIDGE building may be reckoned amongst the earliest of the structural engineers' efforts, and locomotive construction as one of the first lines of development in mechanical engineering, but the adequate study of the actions of a locomotive on a bridge has required very modern resources in investigation, and all those refinements of experimental and analytical methods that mark the engineering technique of to day The problem in its various aspects and complexities has been very completely studied, with the aid of these resources, by the special Bridge Stress Committee appointed by the Department of Scientific and Industrial Research in 1923 The Committee comprised highly representative scientific and technical engineers, under the chairmanship of Sir J A Ewing, of the University of Edinburgh, and the full report of their deliberations and investigations has now been published The remit of the Committee was "to conduct researches with reference to stresses in railway bridges, especially as regards the effects of moving loads" These comprehensive terms of reference have been very adequately interpreted, and the work of the Committee constitutes an invaluable study of the vibration of bridge structures under impact influences Work with a somewhat similar motive had previously been attempted—notably by the American Railway Engineering Association in 1910, and by a special committee of the Indian Railway Board in 1917—but the present report goes much further and deeper into the subject

The previous investigations had made fairly clear that the main cause of serious augmentation of bridge stresses arose from the unbalanced vertical forces developed by the locomotive Certain effects could be traced to rough and flat wheels, irregularities of track, or to heavily loaded freight cars, but these were usually small in relation to the direct consequence of the pulsating force—or 'hammer blow'—due to the 'balance' weights on the locomotive wheels While this was recognised, it has not been very effectively embodied in bridge stress rules, and, as in the well known Pencoyd formula, the influence of impact is generally covered by a proportionate increase, varying with span length, of the live load stress If impact is mainly due to locomotive actions, this process of making allowance on total live load is scarcely rational It is the achievement of the Bridge Stress Committee that it has not only clearly elucidated the nature and cause of impact, but that the investigation is so complete as to permit of the standardisation and rationalisation of impact allowances in general

An ordinary two cylinder locomotive is balanced by the locomotive engineer by the addition of weights to the rims of the driving wheels But this is merely a process of reducing the inertia force effects in the engine lines What is eliminated in those lines is transferred by the so called 'balance weights' to the vertical plane, and hence variation of horizontal force is changed to a vertical fluctuation giving rise to a pulsating force on the rails The magnitude of this force is all important The report repeatedly refers to it, and it is recorded that the locomotive engineers of Great Britain are prepared to limit its value to a total per locomotive of 12½ tons at 5 revolutions per second of the wheels It is, therefore, clear that the importance of the absolute value of this force as a factor in girder stresses is established and accepted The context also explains that, while in some centres special care is taken to test the balance of locomotives after construction, in other cases more attention is required in this matter It is also obvious that three- and four-cylinder, and electric locomotives, in which a much higher degree of balance is possible, have distinct advantages over the more common two cylinder type

The Committee's work consisted of the actual observation of bridge vibrations and the analysis

Greenland as it is and as it was[1]

By Prof A C SEWARD, F R S

IT would not be inappropriate to take as a text for this lecture words borrowed, with a slight modification, from one of Thomas Hardy's novels "The past seizes upon us with its shadowy hand and holds us to listen to its tale" One of my aims is to recall a few scenes—in particular, one scene—from a past separated from the present by an interval measured in millions of years, and by so doing to illustrate an impressive contrast between what is and what was A comparison of a small area of Greenland as it appears to day with the same district as it was at a time roughly corresponding to the stage in geological history represented by the chalk cliffs of England, affords a startling proof of the changing face of the earth and illustrates the fascination and the stimulus inseparable from every honest endeavour to read the secrets of the rocks

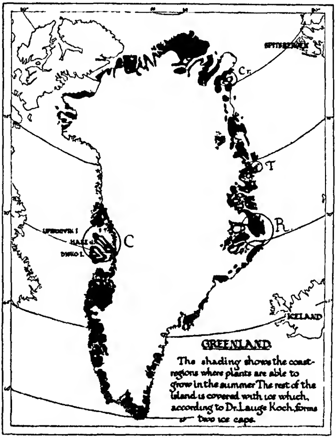

FIG 1—Greenland C, region where Cretaceous and Tertiary plant-bearing beds are exposed Cr locality where a few Lower Carboniferous plants have been collected, T, Sabine Island (Tertiary plants) R Rhætic plant-beds in the Scoresby Sound district

PHYSICAL AND GEOLOGICAL FEATURES

We will first look at Greenland as a whole Cape Farewell, the southern apex of the wedge shaped island, an island large enough to rank as a continent, is approximately on the same parallel as the southern part of the Shetland Islands and as Finland The broad base of the inverted triangle, the most northerly land in the world, reaches lat 83° N, the length is nearly 1700 miles and the breadth in the middle is rather more than 600 miles Greenland is a relatively stable land, one of the oldest pieces of the earth's crust severed from an inconceivably ancient continent which once united the west and the east By far the greater part of the island consists of crystalline rocks of the type we see in the Norwegian mountains and in the north west Highlands of Scotland In the course of ages, Greenland rose and sank with recurrent pulsations of the crust, but the movement was comparatively slight, the sea only partially transgressed the land and advanced farther towards the feet of the mountains

Of these oscillations there is evidence in sandstones and other sedimentary rocks which at several places on the coastal fringe lie on the eroded platform of the original foundations The cliffs of Washington Land on the north-west coast are rich

[1] Friday evening discourse delivered at the Royal Institution on Jan 25

in marine fossils, in places the abundance of corals led the Danish geologist Lauge Koch to describe them as veritable 'coral reefs' Near the north east corner of Greenland some fossil plants were found in sediments deposited in the early days of the Carboniferous period Farther south, at Sabine Island, other sedimentary rocks have yielded impressions of leaves scarcely distinguishable from those of the existing maidenhair tree (*Ginkgo biloba*), with fragments of other plants of Tertiary age Still farther south in the district of Scoresby Sound a rich Rhætic flora has been discovered, a flora no less luxuriant than floras of the same age from much more southern countries The plant fragments were transported by rivers turbid with sand and mud to a delta encroaching over the waters of an estuary at a period between that represented by the still older Triassic salt bearing marls of Cheshire and the younger Jurassic strata exposed on the Yorkshire coast There are also more ancient sedimentary rocks not far from Cape Farewell Special attention will be given in the latter part of the lecture to the remains of a vegetation scattered through sandstones and shales deposited in an estuary during the first half of the Cretaceous period and now accessible in the cliffs of Disko Island, Upernivik Island, and the mainland about half way up the west coast This flora is selected in illustration of the contrast between the present and the past to which reference has already been made

The solid land is seldom stationary, we think of it as permanent, but intensive study of most regions demonstrates the fallacy of conclusions drawn from general impressions Observations made over a series of years in the latter part of last century show that a section of the west coast is now sinking, the brown seaweeds are slowly creeping up the face of the cliffs The Cretaceous plant bearing beds are occasionally overlain by strata of Tertiary age, some of which are rich in plants Both Cretaceous and Tertiary rocks are protected by superposed layers of basaltic lava and volcanic ash—Arctic outliers of the great volcanic plateau of which there are other relics in the Giants Causeway and on islands off the west coast of Scotland Such are some of the documents, differing widely in geological age, which tell of recurrent changes of level and supply the means of interpreting the 'ghostly language of the ancient earth"

A word on the human inhabitants there are about 20,000 Eskimo, most of whom live on the west coast There is a fairly large colony a short distance from Cape Farewell on the east coast, and in 1925 one or two new settlements were established in the neighbourhood of Scoresby Sound. More than 900 years ago, Eric the Red, taking with him about a hundred companions, with sheep and oxen, sailed from Iceland and founded colonies near the south end of the west coast of Greenland In 1721 Hans Egede sailed from Bergen and accomplished what has been called the re colonisation of Greenland, he went there as a missionary in the hope of finding some descendants of the earlier Norse colonists, he found only graves and ruined buildings In recent years many other traces of the early settlers have been discovered by Danish antiquarians In addition to the Eskimo there are a few Danish officials Under Danish rule the condition of the natives has been greatly improved, they can now obtain the necessaries of life whether hunting is good or bad Dogs used for drawing sledges in the northern half of the country are important and, indeed, essential companions to the inhabitants, in summer they are usually left to fend for themselves, in winter they become efficient servants

Greenland under an Ice Sheet

The outstanding feature of Greenland is the inland ice With the exception of a coastal strip along most of the west coast, a relatively broad strip on the extreme north, and a narrow margin on the east, the whole of the island is hidden under ice of unknown thickness which forms a gently sloping dome rising in the interior to a height of at least 9000 ft Here and there on the lower slopes of the ice sheet, summits of mountains project as solitary islands above the "waste of frozen billows" These are spoken of as 'nunataks,' a name suggested by Nordenskjold Sailing up the west coast in summer, one sees the ice free edge of a plateau rising to a height of a few thousand feet, the cliffs intersected by many tortuous fiords, and, on the seaward side, groups of rocky islands with the rounded contours characteristic of ice action An occasional white gleam above the dark cliffs of the mainland comes from the edge of the inland ice Some glaciers creep into the open sea, others enter the deep water of fiords several miles from the coast From one glacier at the head of the ice fiord near Jakobshavn (lat 69° N) are calved many of the icebergs which are carried by currents to the Newfoundland banks and much farther south, many are stranded on shallows off the Greenland coast Near the land the sea is littered with icebergs of all shapes and sizes, their sunlit sides and pinnacled summits are radiantly white, and near the surface of the water a brilliant blue green In the stillness of the night

the sudden booming of breaking bergs recalls Coleridge's description in "The Ancient Mariner" "the ice did split with a thunder fit" Some of the larger icebergs reach a height of 200 ft above the water, and the submerged portion is approximately eight times as deep as the height of the visible berg

The jagged Alpine peaks of the higher mountains of crystalline rock, which are especially impressive as seen off Upernivik Island, are in marked contrast to the flat topped basaltic hills of Disko Island and the adjacent Nugsuak Peninsula (Fig 2) Before passing to the consideration of the fossils preserved in the sediments below the basalt, we will take a general view of the vegetation which partially clothes the ice free coastal belt

FIG 2 Basalt-capped hills of the Nugsuak Peninsula seen from Disko Island (Photo by R E Holttum)

THE PRESENT VEGETATION OF GREENLAND

From the whole of Greenland, 390 species of vascular plants, that is, flowering plants, conifers, and members of the class to which the ferns belong, have been recorded The tree limit, which is taken as the southern boundary of Arctic vegetation, is close to Cape Farewell, in south Greenland there are birches, alders, and a few other trees, some reaching a height of 12 ft or 18 ft Farther north in the region of Disko Island, the only representatives of trees are dwarf shrubby willows and the dwarf birch, the tallest willows rarely exceed three feet The prostrate shoots bear an amazing number of catkins, their roots spread far in a horizontal direction through the shallow soil (Fig 3) The ground is permanently frozen at a depth of rather more than a yard A reflection of the severity of the life conditions is seen in the internal structure of a willow stem, in a section of a stem less than an inch in diameter fifty rings were counted Lichens play a prominent part in the landscape and in preparing the ground for higher plants, tufts of white, yellow, and grey, with splashes of vermilion, give colour to tundra and rock It is worthy of note that about half of the lichens obtained from the Antarctic continent belong to species recorded also from Arctic lands, these wind borne plants are probably the greatest travellers of the plant kingdom The green ribbons marking the course of streams owe much of their brilliance to mosses

There are a few ferns, some growing in rock fissures, some in company with flowering plants in favoured situations *Cystopteris fragilis*, the brittle fern, is one of the most cosmopolitan of plants, it grows in Spitsbergen, in Chile, Abyssinia, on Kilimanjaro, and in the sub Antarctic island of South Georgia There is also the holly fern *Polystichum Lonchitis*, a European species which flourishes in central Asia and in the southern hemisphere Reference may be made to two other plants which belong to the fern class and are very widely distributed *Equisetum arvense*, the common horse tail, and a club moss, *Lycopodium Selago*

Turning to the flowering plants, which give to the Arctic landscape an unexpected brightness, a few examples must suffice The Monocotyledons include several grasses, sedges, and rushes, species of pondweeds (*Potamogeton*) and a few forms of cotton grass (*Eriophorum*) On a sunny slope on the shore of Disko Island there are a few orchids (*Habenaria* and *Listera*) and other plants which have been able

to occupy this exceptionally favoured station many miles north of their normal range The tallest flowering plant is *Archangelica*, an Umbelliferous genus prized as a delicacy both by the Eskimo and sophisticated Europeans The large rounded leaves of an *Alchemilla*, closely allied to the British lady's mantle, come next in size to those of *Archangelica*

There is much heath land, but the heather and ling which we associate with heath moors are absent, their place is taken by *Cassiope tetragona*, characterised by the grooved leaves in four crowded ranks and yellow flower bells *Cassiope* grows in Scan-

FIG 3 —Willows and other plants on a delta below the cliffs of the Nugsuak Peninsula (Photo by R E Holttum)

dinavia, though not elsewhere in Europe, in the Rocky Mountains, and in central Asia The crowberry, *Empetrum nigrum*, associated with the bilberry, is a common Arctic plant which has wandered as far as the southern end of South America Saxifrages are abundant, the flowers of the purple saxifrage, *Saxifraga oppositifolia*, are an exception to the prevailing white This species, one of many common to Greenland and Britain, occurs with other plants on the north coast of Greenland up to lat 83° N, it grows also on the higher slopes of the Himalayas *Dryas integrifolia*, an American species differing but little from the British *Dryas octopetala*, is a conspicuous member of the west coast flora *Dryas octopetala* is characteristic of the north coast and eastern Greenland The familiar and always attractive hare bell, *Campanula rotundifolia*, seems to be as much at home on the hills of Greenland as it is in England, in North Africa, and the Far East Among other plants are the mountain sorrel *Oxyria digyna*, the moss campion, *Silene acaulis*, which is one of several cushion plants characteristic of rocky places, a closely allied plant, *Melandrium apetalum* (or *Lychnis apetala*), the yellow poppy, a species of *Pyrola* (the Labrador tea), *Ledum*, with its white sweet scented flower heads, exceptional in a flora composed almost entirely of scentless flowers, also a willow herb with flowers larger and handsomer than those of our British species

My main object is to give a general impression of the more obvious features of the present vegetation, not to describe many individual plants A Scottish mountain with many immigrants from Arctic lands reproduces in broad features the Greenland landscape, but there is this difference the mountain flora in Greenland reaches the coast and there is no intervening belt of forest and meadow The mean temperature for July in lat 69° N on the west coast of Greenland is 47° F, the corresponding temperature in the London district is 60° F, in February the mean temperature in Greenland is 36° below freezing point, in London it is 10° above the freezing point It is not until the temperature rises above the freezing point that the plant world becomes active in the extreme north the growing season lasts barely two months, it is only in July that rain takes the place of snow In the region of Disko Island the summer season is not much longer The summer is a period of concentrated effort, there is no time for the leisurely sequence of plants that bloom early and plants that bloom late The unfolding of buds prepared in the previous year before the incidence of the winter sleep heralds the rush of new life with an almost explosive suddenness Short

as the summer is, the plants succeed in spreading a parti coloured carpet over hill slopes and valley, and in decorating rock ledges and fissures A brilliant summer display is followed by a "rich autumnal melancholy" the ground is strewn with deep red and orange yellow leaves which are soon to form a welcome blanket, aided by the snow which quickly follows, above the shoots entering on the long winter's rest

Of the 390 vascular plants, Prof Ostenfeld of Copenhagen thinks that about 13 per cent may have been introduced by the early Norse colonists, of the remainder, by far the greater number came from North America by way of the narrow channels separating the American archipelago from the north west corner of Greenland A smaller number travelled from Europe, some driven by wind, the passage probably facilitated by a frozen sea, others carried by birds

Greenland as it is enables us to picture the British Isles in the grip of the Ice Age, at a time separated from the present by a comparatively short interval as geologists reckon time—say 40,000 years We know that the flora of Britain, as also that of northern Europe generally, was much richer in Arctic forms than it is now To give one example from thin layers of peaty material in a gravel pit close to Cambridge, several Arctic species associated with more southern types have been identified, a mixture very similar to that in the present Greenland flora When the Glacial period was at its height, the conditions in Greenland were even more severe than they are now, it is believed by some botanists that the whole of the vegetation colonised the land after the Ice Age had passed its climax The entire vegetation, it is suggested, must have been destroyed On the other hand, the occurrence of flowering plants on the northern border of Greenland and of some species on wind swept island peaks above the level of the inland ice, gives support to Prof Ostenfeld's view that a small proportion of the present flora survived the great ordeal It is highly probable that, as in Greenland to day, a comparatively rich flora is able to exist on the ice free margins and on nunataks, so also when the British Isles were as Greenland is now, there must have been sheltered places which served as refuges for the hardier member of the pre glacial vegetation

Many Greenland plants have a circumpolar distribution, some are exclusively or mainly Arctic, others, though widely spread in Arctic regions, are established also in more southern stations A southern migration from the far north was caused by the gradual extension of the ice, the majority of the plants, unable to endure the increasing hardships, were driven to alien lands and a few crossed the equator When the ice retreated and the temperature rose, some of the travellers returned to the north, others found congenial habitats in the colder climate on mountain slopes A few of the Arctic plants held on to life in their original homes as a small nucleus company in sole possession of a territory temporarily deserted by most of the former occupants

We have noticed the circumpolar range of many members of Arctic floras, and we have seen that some species are able to exist even on the northernmost edge of Greenland which looks out over the abysmal Polar sea Turning to the Antarctic continent, we find an amazing contrast flowering plants are unrepresented on the great mass of land surrounding the South Pole, even though its coast line occupies a position where in the northern hemisphere there is a comparatively rich flora Two flowering plants have been found south of lat 60° S, in South Georgia (corresponding roughly in latitude with the British Isles), the South Shetlands, and Graham Land

THE CRETACEOUS VEGETATION OF WESTERN GREENLAND

We will now visit the cliffs and ravines of Disko Island, Upernivik Island, and the adjacent main land, and glance at some of the fragmentary samples of the Cretaceous flora embedded in the mud and sand of an old river delta We pass over the ages intervening between the maximum glaciation during the Ice Age, which antedates the present by some 40,000 years, to the early days of the Cretaceous period, separated from us by perhaps a hundred million years Among the fossil ferns, by far the most abundant genus is *Gleichenia*, or *Gleichenites*—to use the name generally applied to extinct species Many of the fronds are fertile, and it is possible to examine under the microscope the structure of the spore capsules The habit of the leaves and the structure of leaf stalks and sporangia afford convincing evidence of close relationship with species of *Gleichenia* which are now among the more familiar ferns in the tropics *Gleichenia* is unknown in Europe Another type of fern (*Laccopteris*) is represented by fronds characterised by spreading finger like branches set with long and narrow leaflets which agree closely with those of the Malayan genus *Matonia* Similarly, a few specimens have been obtained which present a striking resemblance, in form and venation, to fronds of another Malayan and Indian genus, *Dipteris*, a plant described by

Alfred Russel Wallace as growing, in company with *Matonia*, on the higher slopes of Mount Ophir in the Malay Peninsula

Leaves, twigs, and occasional petrified stems of conifers are fairly common To-day there are no conifers in Greenland north of lat 67° 50′ N, the northernmost limit of the juniper Petrified stems of conifers rival in size the trunk of a well grown fir, and the annual rings, in marked contrast to those in the dwarfed stem of an Arctic willow, are comparable in breadth with the rings in an English tree Some conifers are represented by innumerable fallen leaves recalling the leaf carpet in a modern forest Imperfectly preserved leaves are untrustworthy as criteria of precise affinity, but such characters as can be made out suggest relationship with the umbrella pine (*Sciadopitys*) of Japan Twigs and occasional cones bear testimony to the occurrence in the Greenland forests of trees akin to the redwoods and mammoth trees which are now restricted to a narrow territory in California Other conifers resemble cypresses, and there is some evidence of the presence of trees allied to existing Araucarias

Two other groups of naked seeded plants (Gymnosperms) are represented broad, wedge shaped leaves with the blade cleft into two or more segments differ in no essential respect from the foliage of the maidenhair tree, the solitary survivor, and that only through the care of man, of a class which once overspread the world The second group is the Cycadophyta, another branch of the plant kingdom which for long ages, in the Mesozoic era, was one of the ruling dynasties and is now represented by a comparatively small family, the cycads or sago palms, which are mainly tropical and reach their northern limit in Florida It is unlikely that the Cretaceous fossil fronds, despite their general similarity to those of living genera, were borne by plants closely related to the true cycads, they probably belonged to species of a wholly extinct section of the group

Finally, we come to the flowering plants the Cretaceous representatives of the class which is now dominant in the plant kingdom were trees, not low growing shrubs or perennial herbs By far the commonest tree or at least the tree which has left the most abundant traces, seems to have been the plane, represented by several forms It must be remembered that the available material, largely consisting of detached leaves, is a small collection of scraps, a random choice of the winds which swept broken twigs and leaves into the waters of a river carrying to its delta a burden of sediment and vegetable debris, records destined to serve as a source book for historians of a future age Our conclusions are based on scraps of evidence, and the only plants we know are such as came within the reach of the agents which caused their preservation In form, in venation, and in size, the leaves of the Greenland planes are scarcely distinguishable from those of trees now living in Mexico, in Greece, and Asia Minor A type of leaf that is abundant at certain localities was for many years believed to belong to a tree nearly related to the tulip tree (*Liriodendron*) of North America and China [2] The examination of more recently collected specimens has confirmed a previously expressed suspicion that the supposed *Liriodendron* leaves are not complete leaves but leaflets from the foliage of trees nearly related to the tropical genus *Dalbergia*, a member of the Leguminosæ Some years ago the late Prof Nathorst of Stockholm described specimens of large leaves and pieces of inflorescence presenting an unmistakable resemblance to the leaves and flowers of *Artocarpus*, the tropical bread fruit tree Some smaller examples of the same type were collected in 1921 The Cretaceous vegetation included other broad leaved trees magnolia, oak, trees related to members of the Laurel family and to species of the family Menispermaceæ now mainly tropical in distribution

It is possible with the help of a little imagination to reconstruct a scene in Cretaceous Greenland Across a broad estuary in summer, a range of mountains on which patches of winter snow are still unmelted, in the foreground maidenhair trees, conifers foreshadowing pines, cypresses, araucarias, and other surviving members of the Gymnosperms There are also many ferns, a few with erect stems, many with creeping rhizomes bearing long stalked and repeatedly forked fronds, others with leaves divided into long, narrow arms Among the broad leaved trees are several planes, an oak, a magnolia in flower, trees with the foliage of dalbergias, the cinnamon, and trees belonging to families which since the Cretaceous period have wandered through Europe and the greater part of the North American continent, some surviving only in the southern tropics

Fossil Plants as Evidence of Climatic Change

An uncritical or superficial comparison of the Cretaceous vegetation with that in the Arctic regions at the present day would seem to necessitate

[2] In a book "A Summer in Greenland," published by the Cambridge University Press in 1922 I referred to these leaves as *Liriodendron* this mistake was corrected in the description of the Cretaceous flora published in the *Philosophical Transactions of the Royal Society* in 1926

the inference that the Cretaceous climate must have been tropical Some of the ferns and other plants obtained from the Greenland rocks have been compared with species that are now mainly tropical in distribution Let us consider more closely the evidence and the conclusions which may legitimately be drawn from it It is true that the existing species of the fern *Gleichenia* are for the most part tropical, on the other hand, the genus occurs in the Far East north of lat 30° N and extends a short distance north of lat 20° N in North America Moreover, the occurrence of species at an altitude of more than 12,000 ft in New Guinea and above 10,000 ft on Ruwenzori in tropical Africa shows that the genus is able to tolerate conditions that are by no means tropical

One of the most remarkable instances of the presence in the Cretaceous flora of a plant that is now tropical is furnished by *Artocarpus* (Fig 4) The genus *Dalbergia* affords an almost equally striking contrast in geographical range The present distribution of *Magnolia* in both the Old and New Worlds is far to the south of its former range The plane tree (*Platanus*) now flourishes in temperate regions, in Greece and Asia Minor, and in America it passes north of lat 40° N The genus *Ginkgo* flowers freely in the south of France, in England it is comparatively hardy The present geographical distribution of such Greenland Cretaceous genera as are now represented by existing species would seem to indicate a climate in the Arctic regions not less genial than that in southern Europe at the present day The important point is the value to be attached to this kind of comparison We know that closely allied species often grow in regions differing considerably in mean temperature

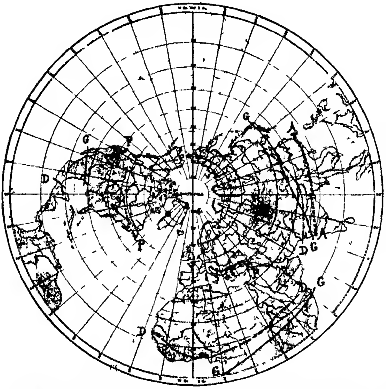

Fig 4 —Map showing the approximate northern boundary of the area of distribution of living species of the following genera A, *Artocarpus* D *Dalbergia* G *Gleichenia*, P *Platanus*

A further point is, ought we to assume that plants have remained unaltered in their constitution, in the sensitiveness of their living protoplasm, to the effects of cold and other external influences? It is surely rash to assume that in the course of ages there has been no change in the degree of response to factors which govern existence My own view is that the practice of employing plants, especially extinct plants, as guides to temperature in the past, has been carried too far There can be no doubt that, when the Cretaceous vegetation covered the western glens of Greenland, the climate must have been very much more genial than it is now, we cannot usefully attempt to estimate the difference in degrees of temperature How can the difference be explained? The often repeated proposal to assume movements in the position of the earth's axis—a shifting of the poles—even were there adequate grounds for the assumption, would not provide a satisfactory solution Astronomers offer no encouragement to geologists prepared to take liberties with the axis of the earth It is certain that the boundaries of land and sea, the height of the land as well as the area, have changed from age to age and that climatic conditions have correspondingly fluctuated Changes in the relative position of land and water, such as we can legitimately postulate, would go some way towards provision of the environment demanded by the Cretaceous vegetation, but it is the opinion of some meteorologists that we cannot solve the problem on these lines

The publication of Wegener's views on continental

drift, the shifting of continental masses by the slow drifting apart of slabs of land detached from a once continuous surface, seemed to offer a possible way out of the difficulty created by the occurrence of fossils in places where their presence has long been a puzzle to geologists We may hope before long to have trustworthy data by which to test the value of Wegener's hypothesis It is tempting to imagine Cretaceous Greenland lying many degrees south of its present position The close correspondence between the Rhætic flora obtained from Scoresby Sound and that discovered some years ago in southern Sweden, and a similar agreement between the Arctic flora and floras preserved in rocks of the same age in Maryland and Virginia, in Bohemia, and elsewhere, almost persuade us that we are most likely to solve the problem by regarding the earth's crust as a collection of blocks floating on a heavier substratum, some of which have wandered far from the positions they once occupied Evidence in support of changing climates is as strong as evidence can be, but we are still groping for satisfying explanations It may be that no explanation can be found unless we adopt the Wegener hypothesis or some modification of it

On the other hand, it is difficult to believe that the greater part of Greenland in the Cretaceous period was not, as it is now, well within the Arctic circle Until we have convincing evidence of drifting continents, the question of how the problem of climatic change is to be solved must be left unanswered Assuming an Arctic Cretaceous Greenland, it follows that the luxuriant vegetation must have been able both to lie dormant during the long winter night and to accomplish the miracle of reclothing the earth in the course of the short summer aided by an ever present sun This unavoidable conclusion, though difficult to accept, is perhaps not beyond the range of possibility

Though we leave unsolved problems raised by the contrast which it has been my aim to illustrate, we have obtained an insight into the methods of deciphering the records of the rocks, records which enable us to reconstruct some of the sharply contrasted stages in the history of an ever changing world

Printed in Great Britain by R & R. Clark, Limited, *Edinburgh*

of the records therein obtained The gross total of the work in the field and in the office is enormous, but the subsidiary work called for in the study of vibration instruments and their accuracy, special small scale laboratory tests, the development of a bridge-oscillating machine, and the theoretical investigation of bridge vibrations, are all of considerable scope and important in themselves Indeed, the analytical work of Prof Inglis is already well known as a research of special distinction, but although it had been, in the main, separately and previously published in special papers, its function in guiding the investigation is only now clearly seen through its relation to the complete report

The pulsating forces from the locomotive wheels create regular impulses on the structure during passage If these are in agreement with the natural frequency of the bridge, large vibratory amplitudes may ensue as a result of resonance The work of investigation, then, entailed the measurement of natural frequencies with the bridge loaded and unloaded, and the observation and recording of the deflections with the locomotive passing over, first at very low speeds, and then at speeds at and around resonance Examinations were carried out on 52 bridges varying in span from 16 ft to 345 ft The locomotives were provided by the railway companies, who throughout co operated with the Committee All types were represented In many cases the engines were specially chosen for the large hammer blow which they developed, so that the worst possible conditions could be fully observed The total amount of information gathered, and the wide range of spans dealt with, full particulars of which are given, certainly permit of important conclusions which should prove thoroughly reliable in the guidance of bridge design

The limitation of the amplitude of vibration in any case is partly an effect of damping, and in this connexion the interesting work on the influence of the locomotive springs should be noticed There is apparently a pair of critical speeds depending on whether the suspension springs are in play or not, the probability depending on whether the oscillations of the bridge are sufficiently great to overcome the spring friction Apart from damping, however, the span length is an all important factor With short spans the natural frequency is too high to be equalled by the locomotive speeds With very long spans, on the other hand, the natural frequency agrees with low locomotive speeds, when the impulses are relatively small To deal with these different effects the Committee develops a 'dynamic magnifier,' a multiplier akin to the usual amplification factor of vibration theory, which expresses the ratio of the vibration amplitude to the deflection that would be caused by a static load equal to the hammer blow This factor is first developed for the synchronous condition for all spans and then corrected for the interrelations of span length and locomotive frequency It would appear that spans around 100 ft are subject to the largest dynamical magnification The curve for this important factor should ultimately take an important place in bridge design rules

The report briefly discusses other causes of impact, such as effects of irregularities of track, rail joints, and the 'lurching' of locomotives, and enters at large into the tabulation of loads and allowances for impact Appendixes on impact formulæ, instruments, balancing of locomotives, etc, are given The whole report constitutes an impressive compilation of the details and conclusions of a courageous and exhaustive full scale research that reflects great credit on the Committee and its staff

Obituary

THE issue of the *Physikalische Zeitschrift* for Jan 1 contains a photograph and an obituary notice of Prof A H Bucherer of Bonn, who died in May 1927, written by his former colleague, Dr R Tomaschek He was born in Cologne on July 9, 1863, the eldest of six children of H Bucherer, a chemical manufacturer, and his wife, a musical and highly educated English lady He was educated at the Cologne High School, where he displayed a gift for languages After serving his year in the army and spending a year at the Hanover technical school, he went in 1885 to the Johns Hopkins University, Baltimore, where he studied under Prof Ira Remson, and for a time held a lectureship, then in 1893 to Cornell University, and in 1895 returned to Germany to complete his studies under Prof Braun at Strasbourg, and took his doctor's degree in 1896 After a further three years at Leipzig under Ostwald, and at other universities, he became a lecturer on physical chemistry at Bonn in 1899 Later he became honorary professor, a post he resigned in 1923 From his youth he showed himself of independent thought, little disposed to conciliate those from whom he differed, and this attitude did not smooth his way in life He is best known for his "deformable electron" and for his experimental determination of the influence of the speed of an electron on its apparent mass He was not satisfied with Einstein's relativity theories, and was engaged towards the end of his life in an endeavour to deduce all the results of that theory and remove some of the difficulties it has raised, by a logical development of classical mechanics

---

BY the recent death of Dr Franz Oppenheim, announced in the *Chemiker Zeitung*, Germany has lost one of its leading personalities in chemical industry For nearly fifty years Dr Oppenheim was associated with the Aktiengesellschaft für Anilinfabrikation in Berlin, of which concern he was president at the time of its inclusion in the I G Farbenindustrie Aktiengesellschaft in 1925 His ripe experience led to his appointment on the board of management of the latter amalgamation He held several public offices connected with the German chemical industry, for example, he was treasurer of the Emil Fischer Society for the promotion of

chemical research, of the Adolph von Baeyer Society for the promotion of chemical literature, and of the Justus von Liebig Society for the promotion of chemical teaching Quite recently he had been elected to the committee of the Chemisch Technische Reichsanstalt in Berlin He died at Cairo at the age of seventy seven years

The death on Feb 28, at the age of seventy three years, of Dr J Wells, formerly Warden of Wadham College and Vice Chancellor of the University of Oxford, is felt as a serious loss in many departments of University activity Though not himself a student of science, he was never unmindful of the scientific traditions of the College over which he presided It is undoubtedly the case that but for his wise and fair minded dealing with the matter during his vice-chancellorship, the Lewis Evans collection of scientific instruments might have been lost, not only to Oxford, but to England as well It should always be remembered that not only this invaluable asset for the history of science, but also many other advances in the scientific equipment of the University of Oxford, owe their efficiency, if not their existence, to the good offices of Dr Wells

News and Views.

The fiftieth birthday of Prof A Einstein occurred on Mar 14 and brought congratulations from all parts of the world The German Chancellor hailed him as "Germany's great savant," and the Berlin municipality gave him the life tenancy of a pleasantly situated mansion The University of Paris conferred an honorary degree The Zionists are to plant an "Einstein Wood" near Jerusalem Never before has the name of a scientific worker meant so much to the average man Yet the creator of relativity and of the unitary field theory remains a quiet and retiring personality who dislikes publicity and society His appearance suggests a musician, and indeed his love of music is one of his leading characteristics Last year he gave a violin recital for a charity He finds much pleasure in Russian literature, and appreciates modern ideas in architecture He is an ardent sympathiser with efforts for world peace Recently his health has not been good, but he says, "Illness has its advantage one learns to think I have only just begun to think"

Employers and trade unionists associated under the auspices of the Conference on Industrial Reorganisation and Industrial Relations have recently issued an interim joint report on unemployment In this report the problem of unemployment is investigated and suggestions made for its diminution It is pointed out that, since 1920, there have seldom been fewer than a million workers unemployed in Great Britain, while at times the number has exceeded two millions The heavy industries in particular have been severely hit by the depression and the activity of certain prosperous industries, such as artificial silk and the motor industry, has not really compensated for this depression in the great basic industries The report stresses three factors, monetary policy, world economic conditions, and the temporary displacement of labour due to the rapid adoption of labour saving methods, as being the main causes of the present acute unemployment.

Corresponding to this analysis of the causes of unemployment in Great Britain, the main remedies (that is, apart from immediate or merely palliative measures) suggested in the recent interim report are *first*, an inquiry into monetary policy with whatever action may be found necessary, *second*, the reorganisation of industry, including rational organisation into larger units and the substitution of modern plant and technique, and *third*, measures to mitigate the evils resulting from rapid displacement of labour Finally, the novel and interesting suggestion is put forward that a Labour Reserve Fund should be set up either by firms or by particular industries, which fund would be available for the purpose of assisting displaced labour Progressive firms, it is pointed out, build up special reserve funds (apart from normal depreciation) to enable plant to be replaced before it is worn out, so that the most modern equipment can be introduced It is even more necessary that such progress should not involve hardship to the human element

Industrialism in England moves on apace and the town continues to swallow up the countryside This is a healthy economic sign even though it leads to unhealthy social conditions The old order of towns and villages is giving place to new groups of towns or 'conurbations' and regional associations Mr F Longstreth Thompson in his address on 'Recent Developments in Town Planning,' read at the Surveyors' Institution on Mar 4, enumerates no fewer than 67 joint committees covering a total area of almost 12,000,000 acres and having a population of approximately 30,000,000—out of a total population for England and Wales of only 38,000,000 In view of the near approach of the next census, this raises a question of great importance Hitherto the statistical information has been given separately for the towns, the urban and the rural districts This assumes an economic isolation which no longer exists, and serious consideration should be given to furnishing returns on the basis of these new divisions which have developed by and from the recognition of mutual dependence and interests For the sake of continuity it may be essential to maintain the earlier census divisions, but supplementary summaries may at least be possible

Returning to Mr Thompson's paper, he points out two useful outgrowths from the original Town Planning Act For the moment, town planning schemes are confined to land which is in course of development or appears likely to be used for building purposes For boroughs and urban districts with a population

of more than 20,000, such schemes are obligatory, though the date of their completion has been twice postponed The fact that other communities have organised themselves voluntarily for the preparation of a scheme shows that regional and town planning is now accepted as part of local administration The latest developments have been in the direction of controlling areas already built upon The Minister of Health now has powers to act with the view of preserving the existing character and protecting the existing features of any locality of special architectural, historic, or artistic interest Advantage has already been taken of this permission to prepare schemes for Oxford, Winchester, Exeter, and Canterbury Mr Thompson notes also that official consideration is being given to the question of extending town planning powers in respect of all built on areas and that it may be anticipated that the scope of the Act will be enlarged in this sense in the not distant future

AT the time of writing no detailed account has appeared of the circumstances attending the commencement of the disastrous floods that began on Mar 13 in Alabama, U S A, owing doubtless to the speedy interruption of communications between the devastated area and the outside world In the *Weekly Weather and Crop Bulletin* of the U S A Department of Agriculture, it is stated that in January a large part of the States northwards and northwestwards from the Ohio and Missouri valleys had extreme cold, with heavy snowfall, which in some places exceeded anything known before in January The rainfall over Alabama for that month was, however, not remarkable In February there was an equally pronounced area of cold, rather farther south than that of January, the distribution of excessive precipitation was different and covered a smaller proportion of the country, Alabama lying, however, well within the most notable wet region, which included the Atlantic coastal States and extended south westwards to the Lower Mississippi River Within this wet zone the fall was sometimes more than twice the normal for the month The same publication contains a note of excessively heavy rains over parts of Alabama early in the present month, and of the rivers Tombigbee and Coosa being in flood before the end of the first week

MORE recent meteorological information is available on the charts for the northern hemisphere published by the Meteorological Office, London Between Mar 10 and 12, a large anticyclone moved eastwards from a position south of the Great Lakes A long chain of depressions which extended from Alaska southwards to the western part of the Gulf of Mexico, if not still farther, began to replace the anticyclone and brought wet weather with southerly winds and rising temperatures to the Gulf States Cyclonic weather appears to have continued at least up to Mar 16, that is to say, for three days beyond the date when the floods are reported to have begun The southerly winds evidently extended from regions well within the tropics, and must have been heavily charged with moisture It is reasonable to suppose that the work of the tropical rainstorms may have been aided by rapid melting of the snow on high ground farther north, and that the overcharged rivers burst their banks or 'levees,' as happened in the Mississippi floods of 1926–27 Such disasters, and the more frequent devastations on a smaller scale due to travelling 'tornadoes,' are inevitable in a country where the gradient of temperature with latitude in early spring is so steep It is the presence of the tempering waters of the North Atlantic in high latitudes that saves the British Isles from like visitations

SEVERAL of the Livery Companies of the City of London have made very substantial provision for the development of science and technical education, and it is estimated that the amount actually expended by them on these objects exceeds two million pounds Some of the companies have established scholarships or fellowships, in addition to making grants to institutions Thus the Grocers' Company has three scholarships of £300 a year each, for inquiry into causation of prevalent disease or as to means of prevention of premature death, the Salters' Company has founded its Institute of Industrial Chemistry, which offers fellowships of £250 to £300 a year to chemists of graduate standing to enable them to undergo a special further training for careers in chemical industry, the Drapers' Company has devoted £20 000 to scholarships for the textile industries, and similar endowments have been made by the Leathersellers' Company and the Fishmongers' Company About six years ago the Armourers and Brasiers' Company founded its research fellowship in metallurgy, which is awarded by a committee consisting of three persons appointed by the Company and four appointed by the Royal Society and is of the value of £500 a year Miss C F Elam has done very successful research in metallurgy while holding this fellowship for the past five years, and she still has another six months in which to continue her work Announcement is now made that a new fellow will shortly be appointed Full particulars of the fellowship can be obtained on application to the Secretaries of the Royal Society, Burlington House, London, W 1

WIDESPREAD interest has been aroused by the announcement made by Mr Leonard C Woolley in the *Times* of Mar 16 that he has discovered at Ur evidence for the historicity of the Flood of Genesis and Mesopotamian legend In excavating the deposits belonging to the early occupation, to which reference has been made in previous communications, he found relics of human activity on the low lying parts of the island which had been submerged under a huge bank of water laid clay of some eight feet in thickness On top of this was a fresh occupation which carried on some of the old traditions but departed entirely from others There is thus a break in continuity caused by this disaster which he suggests can be none other than the flood of Sumerian history and legend

COMMENTS by Sir E A Wallis Budge and others appear in the *Times* of Mar 18, and they generally

accept Mr Woolley s suggestion The most interesting comment is that made by Prof S Langdon of Oxford who has revealed some hitherto unpublished evidence from the expedition at Kish which conclusively points to the historical nature of the Bible story At Kish where excavations have been carried down to virgin soil, are two precipitations of clay containing potsherds and stranded fish lying perfectly horizontal in a way which could only be the result of a flood This flood took place between 3400 B C and 3200 B C Another deposit of a similar character on the water level is dated at about 4000 B C Prof Langdon is inclined to regard the flood of Genesis as the one between 3400 B C and 3200 B C, which he connects with the Sumerian legend of Ziudzudra, the last of the antediluvian kings in the traditional royal lists who built a boat to escape the waters This legend was incorporated in Babylonian story and thence reached the Hebrews In view of the extreme interest of this theory, it is scarcely necessary to stress the importance of securing continuity of excavation at both Ur and Kish We hope that public interest may be stimulated by this latest discovery to provide the necessary funds

It is now more than six years since the inauguration of broadcasting produced a world wide demand for a loud speaker A paper by R P G Denman on the development of these instruments was read to the Royal Society of Arts on Mar 13 The early forms of loud speakers were incapable of radiating sound the frequency of which was below about middle C (256) This was not at first recognised as the ear has a marvellous power of reconstructing a mutilated complex tone A pure tone is essentially a single vibration which follows the sine law In a complex tone we have one or more overtones in addition The B B C recently carried out experiments to determine the minimum value of the amplitude of the second harmonic which must be superposed on the first harmonic so that it becomes noticeable in an ordinary loud speaker

It was found in the B B C experiments that when the frequency of the fundamental was 900 the amplitude of the second harmonic has to be at least 3 per cent of the amplitude of the fundamental before it becomes audible At higher frequencies a much greater percentage is necessary When the frequency, for example is 5000 the percentage of the amplitude of the second harmonic required for audibility is 49 The introduction of cone loud speakers and the annulment of resonance effects by frequency filters were notable steps in advance The efficiency of transformation of all ordinary loud speakers is very low Some of the loud speakers however used in the commercial operation of Movietone and Vitaphone talking film systems have efficiencies of 30 per cent A new Western Electric loud speaker is claimed to have a fifty per cent efficiency It seems probable that great improvements will be made in the near future in the instruments used in theatres and that the small domestic loud speaker will either remain as it is or become similar to a small auditorium instrument

At a meeting of the Section of Neurology of the Royal Society of Medicine, held on Mar 14, a kinematograph demonstration was given of a film, showing some of the experiments on conditioned reflexes done in Prof Pavlov s laboratory at Leningrad Although the work and conclusions were familiar to most of the audience, yet it was obvious that the film proved interesting giving, as it did, a reality to experiments hitherto known only through verbal descriptions in text books The film is not intended for the general public, but as a means of illustrating lectures for students as such it certainly seems to have many advantages There is, however, a possibility of danger, for it would be very easy to select a series of experiments because they happen to illustrate a thesis and to omit the negative instances the arresting nature of the presentations renders this more serious than in any other form of exposition There can be no question as to the scientific value of Prof Pavlov s experiments but the deduction therefrom that man is nothing but a bundle of conditioned reflexes is fallacious The Society is to be congratulated on the novel and provocative form of meeting

The controversy about the future development of the Bodleian Library has been closed by the acceptance of a decree in Congregation authorising the University Chest to receive subscriptions for the carrying out of a definite scheme of extension The scheme is of the nature of a compromise and is probably not thoroughly satisfactory to any of the interested parties It involves the transformation of part of the north side of Broad Street one of the characteristic features of Oxford and also the removal of some of the Bodleian stores to a site three miles distant from the city A recent decision of the Curators to exclude certain kinds of literature considered to be of merely ephemeral value gives rise to some difference of opinion, many people holding that publications of this kind may become with the lapse of years, of great interest and importance as illustrating manners and modes of life of the present day

The Zoological Society of London celebrates this year the centenary of the granting of its Royal Charter in 1829 three years after the formation of the Society itself and an announcement has just been made of the manner in which the occasion is to be commemorated The large number of fellows of whom there are now more than 8000 has made necessary the arranging of more than one function A centenary celebration meeting will be held in the Great Hall University College Gower Street, on April 29 when centenary speeches will be delivered and official and foreign guests will be present In the evening of the same day the foreign and official guests will be entertained to dinner by past and present members of council and other officials of the Society The greatest gathering of all will be a centenary celebration garden party, to be held at the Society s Gardens on the evening of June 20, and to this every fellow will receive an invitation for himself or herself and one guest In an earlier note we referred to the historical account of the development of the Society to be written by Dr P

Chalmers Mitchell, and we understand that this interesting volume is well advanced

As recently announced by the Prime Minister of the Commonwealth of Australia, the Commonwealth Government is promoting an expedition, under the leadership of Sir Douglas Mawson, for scientific and survey work in the Antarctic lands lying south of Australia The British Government is making a financial contribution sufficient to enable the R R S *Discovery* to be placed at the disposal of the Expedition It is anticipated that the investigations will occupy two seasons, from the summer of 1929 to the summer of 1931 Every effort will be made to maintain the closest co operation between the Australian work and that already in progress under the *Discovery* Committee, and in order to assist in securing complete uniformity of method a member of the *Discovery* staff will be seconded for service with the Australian Expedition In view of the loan of the *Discovery* to the Australian Expedition, the Secretary of State for the Colonies has sanctioned the construction of a ship which, with the *William Scoresby*, will enable the work of the *Discovery* Committee to be continued The new vessel will be a steamship with a superior radius of action, and will be able to undertake long ocean traverses for which the *Discovery* is not well suited She will carry echo sounding gear and also a specially designed winch, carrying 5000 fathoms of wire rope, for working large nets at any depth For smaller nets and hydrological observations three auxiliary machines will be provided Large biological and chemical laboratories on the upper deck, a photographic room and a survey office, workshop store rooms and other accommodation necessary for the intended service are being provided In addition to a full complement of executive officers, she will carry a scientific staff of six and a survey officer, the total of officers and crew being about fifty The vessel is being constructed at Port Glasgow by Messrs Ferguson Bros (Port Glasgow), Ltd

ON Tuesday, Mar 12, Dr H Przibram, professor of experimental zoology in the University of Vienna, delivered, at the request of Prof E W MacBride, a lecture on the "Transmission of Acquired Modifications from Parent to Offspring" in the Imperial College of Science Dr Przibram commenced by referring to the four postulates in Weismann's theory of natural selection, and stated that every one of the four has proved to be untrue He also referred to theories of Mendelian inheritance, depending upon 'genes,' which would require modification in the event of the discovery that acquired modification could be transmitted to offspring Dr Przibram pointed out that although no one sufficiently skilled to be able to repeat the work of his pupil, Kammerer, on rearing Amphibia for several generations had yet appeared, Kammerer's results, so far as the effects of the environment on one generation are concerned, had received abundant confirmation in recent years, the latest of these being the discovery in the Jardin des Plantes in Paris of a strain of *Alytes* which bred in or near the water, in which the males had vestigial 'nuptial pads' on their hands

DR PRZIBRAM described a long list of experiments made in recent years which had given evidence of the transmission of acquired characters Many of these have been performed in his own laboratories under his supervision, and incidentally he remarked that the fact that some people had tried to repeat them and failed was no disproof of their validity, for in experiments of this kind where conditions are complicated, the failure to get one condition out of the whole number right was sufficient to upset the experiment Perhaps the most interesting part of the lecture was that in which Dr Przibram outlined his attempt to analyse how environmental effects are transmitted to offspring, thus rats brought up in high temperatures have longer tails than those bred at low temperatures, but the heat of the air does not act directly on the growth of the tail, but indirectly, by stimulating metabolism and increasing body temperature One is involuntarily reminded of that far seeing dictum of Lamarck's "But what ever it does, the environment never directly affects the growth of an animal, but indirectly by altering its needs necessitating fresh efforts on the part of the animal to satisfy them, causes it to use some parts more than others and so stimulates their growth"

IN the course of an address on "Road Transport," read before the Junior Institution of Engineers on Mar 8, Mr S H Hole stated that the first practical mechanically propelled road vehicle was the steam tractor built by Cugnot in 1769, which carried four persons and attained a speed of $2\frac{1}{2}$ miles per hour, an improved type was designed to carry $4\frac{1}{2}$ tons at the speed mentioned, and cost £800 In 1798, Trevithick and Vivian patented inventions relating to high pressure steam in connexion with locomotion, and in 1803 had a road vehicle in operation in the streets of London Between 1827 and 1830, steam coaches were in operation between Gloucester and Cheltenham which had an average speed of 12 miles per hour with a maximum of 20, and they were operated successfully in London until Parliament enforced tolls in the proportion of 12 to 1 as compared with the four horse coach, and they thus fell into disuse A still further check to the progress of mechanical transport was the Act passed in 1865, limiting the speed of mechanically propelled vehicles in the country to 4 miles and in towns to 2 miles per hour, with a flagman in front The years 1906 and 1907 saw important changes in motor car design, when magnetos replaced coil and battery ignition and the worm drive to the live back axle, coupled with a differential gear, was built by Lanchester The more rapid development in mechanical transport, both for goods and transport, during the past twenty years, has been due largely to research on the properties of special steels, this has enabled great reductions in weight to be made without sacrifice of reliability The progress in machine tools and in the scientific balancing of engines, especially for aeroplane purposes, have all aided the evolution of the modern car Further lines of progress will be in the number and positioning of cylinders, higher speeds of engines combined with decreased weight and greater flexibility

The dramatic element in aerial flight has always appealed to the popular press and would have succeeded in maintaining a live interest in that subject whether the technical men were active in it or not, but the scientific interest has been steadily pursued, and the time is rapidly approaching when special journals will require to be produced to cater particularly for this development Germany has already a number of journals of this type In Great Britain we have been very prone in the past to maintain our scientific journals in omnibus type, and only workers in such specialised fields realise the difficulties involved in digging out and collecting the papers they are concerned with from these various miscellaneous journals, our scientific press is certainly not scientifically organised On the aeronautical side, the reports of the Aeronautical Research Committee have in this respect pursued a very effective policy, but they suffer from two disadvantages They are in the first place almost entirely confined in their publications to the work which is being undertaken in Government research establishments in the second place, they are issued to the public almost a year after the work has been executed Scientific workers, therefore, not professionally in immediate contact with these places, but striving to work in these fields, must continually lag behind in respect to any developments that have occurred No doubt there are difficulties in the way of earlier issue to the public A new journal, styled *Aircraft Engineering*, under the able editorship of Lieut Col W Lockwood Marsh, has now made its appearance—an old title for a new paper In format it is not unlike *Engineering* itself, but it is a monthly journal and restricts its attention to those matters of direct interest in the design and construction of aircraft and in research work on aerodynamics It is intended to be a scientific and technical journal for aeronautical engineers and research workers The first issue in March contains, among other important articles, a résumé of the research and technical progress in 1928, special discussions on stream lining of air cooled engines, on a new theory of tail flutter, and on the efficiency of the auto gyro If the standard of succeeding issues can be maintained, this journal should play a very important part in the concentration of aeronautical publication

According to the annual report of the U S Bureau of Standards for the year ending June 1928 (Washington, D C Government Printing Office, 5 cents) the work of the Bureau has been divided into two groups, the first dealing with scientific research and testing, the maintenance of standards and their improvement, the second with the supervision of commercial standards with special reference to the needs of industry The regular staff now numbers 860, and the salaries 572 thousand dollars per annum The fee values of the tests carried out by the Bureau were for the public, 67 thousand dollars, for the Government and States, 351 thousand dollars, and for the Bureau, exclusive of research and standardisation tests, 46 thousand dollars Upkeep of the buildings, plant and grounds has cost 83 thousand dollars and additions 88 thousand dollars. The work done is summarised under various headings, the total cost of each group is stated, and ten or a dozen lines are devoted to a description of each research of the group

In order to test structural and miscellaneous materials, the Bureau of Standards maintains three branch laboratories, one at Northampton, Pa, one at Denver, Col and one at San Francisco These branch laboratories are fully occupied, and there is need for increase of personnel and equipment to cope with the ever growing increase in the work In view of the hazardous tests sometimes carried out at the Bureau a demand is made for a first aid station under the care of a competent physician Elaborate apparatus has been constructed in order to obtain a more accurate value of the constant of gravitation, as a knowledge of this constant is necessary in many tests The tests made with metal furniture prove that the fire risk is considerably diminished by its use Metal shelving in particular prevents a fire from spreading The large variation in the index of refraction of lead glass with the annealing temperature has been investigated Good practical work has been done in developing radiobeacons for aeroplanes A demonstration between two air ports was given of a new type of beacon which produces visual signals on an instrument on the aeroplane board Aeroplanes fitted with these instruments can fly perfectly safely in fog or darkness between these ports although no landmarks are visible

The Council of the Royal Society of Edinburgh has awarded the Gunning Victoria Jubilee Prize for the period 1924–28 to Prof Edmund Taylor Whittaker, in recognition of his distinguished contributions to mathematical science, and of his promotion of mathematical research in Scotland and the Makdougall Brisbane Prize for the period 1924–28 to Dr W Ogilvy Kermack, for his contributions to chemistry, published in the Society's *Proceedings* and elsewhere

The Council of the Iron and Steel Institute has this year decided to present its Carnegie Gold Medal to Dr Arthur Bramley, head of the Metallurgical Department of the Loughborough College The Medal which was founded by the late Mr Andrew Carnegie, is awarded to the research worker who, in the opinion of the Council, has produced the most meritorious piece of research work in each year under the scheme of the Andrew Carnegie Research Scholarships of the Institute

At the invitation of the Société Française des Électriciens, the summer meeting of the Institution of Electrical Engineers will be held in France on June 11–22 The Paris Orléans and Midi Railways are providing railway transport free of charge for a trip to the Pyrenees, and the Chemin de Fer du Nord will transport the party between Calais (or Boulogne) and Paris at half fare Numerous visits to works and places of interest are being arranged

A public meeting on Developments of British Chemical Manufactures has been arranged by the British Science Guild and will be held in the Mansion House, E C 2, on Wednesday, April 24, at 4 30 P M, when the Rt Hon Lord Melchett, president of the

Guild, will take the chair The programme will include the following addresses (1) "Fertilisers from the Air," by Sir Frederick Keeble, (2) "Rayon (Artificial Silk)," by A B Shearer, and (3) 'Synthetic Drugs,' by F H Carr Tickets for the meeting may be obtained on application to the British Science Guild 6 John Street Adelphi, W C 2

A SEVERE earthquake occurred in the North Atlantic on Feb 22 at 3 41 P M The position of the epicentre is given by the seismologists of the U S Coast and Geodetic Survey as approximately in lat 10° N, long 42° W, or about a thousand miles from the mouth of the river Amazon (*Daily Science News Bulletin*, Science Service, Washington, D C) This region is one of the belts of seismic activity in the Atlantic Ocean and was the scene of a severe earthquake in October 1925, recorded by instruments all over the world As it also lies along the course of vessels between New York and Pernambuco, the shock must have been felt on any passing ships as if the vessels were grating on the ground below

A NEW part (No 813) of Sotheran s invaluable "Catalogue of Science and Technology ' has reached us Its designation is Part IX XIII Engineering, Section 1 and gives the titles of and much bibliographic information respecting periodical publications, early works to the end of the eighteenth century and general works including lives of engineers The list can be had upon application to the publishers, 140 Strand W C 2

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —Temporary assistants and temporary sub assistants in the Herbarium of the Royal Botanic Gardens Kew—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S W 1 (April 8) A sub inspector of quarries in the Midland and Southern Division of the Mines Inspectorate—The Under Secretary for Mines Establishment Branch, Mines Department Dean Stanley Street Millbank, S W 1 (April 20) A secretary of the Institute of Physics and editor of the *Journal of Scientific Instruments*—The President Institute of Physics, 1 Lowther Gardens, S W 7 (April 21) A director of extra mural studies in the University of Birmingham—The Registrar, The University, Birmingham (April 27) A clinical pathologist at the Crichton Royal Mental Hospital—The Physician Superintendent Crichton Royal Mental Hospital Dumfries A clinical bacteriologist at the Cheshire Joint Sanatorium Market Drayton The Medical Superintendent Cheshire Joint Sanatorium Market Drayton A male junior assistant under the Directorate of Ballistics Research Research Department, Woolwich—The Chief Superintendent Research Department, Woolwich

Our Astronomical Column

A PROBABLE NEW TROJAN PLANET —The Trojans are a group of minor planets the period of revolution of which is the same as that of Jupiter, and which maintain an approximately constant position relatively to Jupiter, four of them, Achilles Hector, Nestor Agamemnon are 60° in front of Jupiter while Patroclus and Priamus are 60° behind it *Beobachtungs Zirkular* No 7 states that Nestor was photographed by Dr Reinmuth at Konigstuhl on Feb 9, on the same plate, 46 east of Nestor and 36 north of it, another planet was found with the same motion as Nestor in Right Ascension (− 0 5 m daily) This is much slower than the average retrogradation of the asteroids when near opposition, and makes it probable that the new body belongs to the Trojan group Its provisional designation is 1929 CM It is slightly brighter than Nestor, their magnitudes being 14 2 and 14 8 respectively 31 new planets were discovered in the first half of February

THE SPECTRA OF COMETS —The theory of Schwarzschild and Kron on the nature of comets tails is extended by H Zanstra in the *Monthly Notices* of the Royal Astronomical Society, vol 89, p 178, to explain the line and band spectra of the heads. It is suggested that the observed lines are resonance lines producible under low excitation, or in some special instances are caused by fluorescence, in other words, sunlight is absorbed by the gases of the comet's head and then re emitted in the same (or sometimes longer) wave length The intensity of the spectrum to be expected from this theory is computed and compared so far as possible with actual observations The result seems to show that the theory is quite sufficient to account for the observed luminosity in the case of such comets as are considered, though some of the very bright comets with only one known apparition may provide a severer test One example of such comets (Comet Wells 1882) is discussed in some detail The *D* lines of sodium were observed to be very nebulous which is in agreement with the requirements of the theory while the iron lines noticed in this comet are capable of explanation by fluorescence

THE UNIVERSITY OBSERVATORY OXFORD —The report of this Observatory for 1928 has been issued It records the completion of the measurement of the plates taken at the Vatican Observatory for the Astrographic Catalogue and sent to Oxford for measurement the Pope has presented medals to the director and his assistants in recognition of their share in this work The zeal of the director Prof H H Turner for the completion of the whole Catalogue is well known He has undertaken to complete the southern portion (+ 32° and + 33°) of the zone originally allotted to Potsdam The northern portion is being undertaken at Hyderabad, and it is hoped that the middle may be filled in by an observatory in the United States

Allusion is made in the report to Dr Fotheringham s work on the Venus tablets of Ammizaduga, in conjunction with Prof Langdon, and to his studies on the relation between Babylonian and Greek astronomy, with special reference to Naburianos and Cidenas

The new buildings in the Observatory have been completed The seismographs have been moved there from the Clarendon Laboratory The upper rooms afford a much needed extension to the Library Five papers and reports on seismology by the Director have been published since the last annual report The coelostat belonging to the Observatory has been lent for the expedition to Siam to observe the total solar eclipse of May 9

Research Items

NEOLITHIC FAYUM POTTERY.—In *Ancient Egypt*, 1928, pt. 3, Miss G. Caton Thompson has released in advance an account of the neolithic pottery of the Fayum pending adequate publication of the material collected in the three seasons' investigations, of 1924–1925, 1925–26, and 1927–28. The bulk of the material is from a larger midden settlement, Kom W, of more than 600 ft. by 400 ft. and about 5 ft. deep. It belongs almost entirely to the earlier Neolithic or Fayum A period. Other and better preserved vessels came from straw lined granaries. Some were found singly in other parts of the desert. All the pottery is handmade in coarse clay with straw as a *dégraissant*. Unequal and insufficient firing has produced a grey mottling on red pots, the core in nearly all cases being black and soft. Owing to the combination of organic matter from the midden and the salt of the desert, the texture has suffered and few pots retain their original surface. Many of the pots were rough faced and devoid of slip and burnish. Some may originally have had a slip. A polished ferruginous wash and a burnished black finish were frequently used. One class (class 5) is associated with a thin ferruginous slip, polished and of a purple red colour similar to the old Nile Valley pre-dynastic wares. Black polish is rare. A few sherds were hand smoothed. The forms are grouped into five classes: (1) Small bowls and cups; (2) cooking bowls or pots—these two classes being of the type common to all primitive ceramic development; (3) pedestal cups, an important class suggesting the prototype of rare and early Nile Valley pre-dynastic vases—this form occurs in the Middle Neolithic stratum at Knossos; (4) cups, with legged bases—poorly represented; (5) rectangular dishes with 'peaked' rims—a type which appears to have no parallel in the pre-dynastic period.

MILK YIELD OF DAIRY COWS.—A statistical analysis of the data of the Scottish Milk Records Association by Dr. J. F. Tocher has been issued by the Biometric Laboratory, University College, London (*Biometrika*, vol. 20, B, pt. 2, p. 105; 1928). There is a distinct improvement in the milk yields of recent years compared with those of twenty years ago, from an average of 16½ gallons to one of 18½ gallons per week. The yield per week is shown to vary with age of cow. Young cows give an average of less than 16 gallons, whereas cows of 9–11 years give more than 20 gallons. There has also been an average increase in total butter fat, amounting to 7 per cent. The monograph is profusely illustrated with diagrams and photographs, and contains a number of tables, some of which should be of value to the practical dairy farmer. For example, there are tables showing the yield of milk for each stage of lactation period, and one showing the average amount of butter fat obtained for cows of a given age and for a given length of lactation period. A farmer could thus compare the actual yield of a cow with the average, and so determine whether she is up to standard.

CONTROL OF POWDER POST BEETLES.—Beetles of the genus *Lyctus* are commonly termed 'powder post beetles' from the fact that their larvæ bore into timber and, as a result, give rise to the production of a fine powdery dust or 'frass'. Particular attention has been paid to these insects at the Forest Products Laboratory at Princes Risborough, and the result of recent inquiries are embodied in *Bulletin* No. 2 (1928), Forest Products Research, by Dr. R. C. Fisher. Evidence has been collected which indicates that the increase and spread of these insects in Great Britain since the War have been due to the importation of infested American ash and oak. Among the most notable facts stressed in this *Bulletin* is the egg laying habits of these beetles. In the species studied the eggs are always inserted within the vessels or pores of the wood, whether they be transversely or horizontally exposed, and are never laid on the surface. It is therefore impossible to see a *Lyctus* egg except by microscopical examination of the wood. A definite correlation has been found between *Lyctus* attack and the size of the vessels in different kinds of wood. So far as is known, the insects never attack conifers, probably owing to the absence of vessels or pores in which their eggs could be placed. Not all hard woods are attacked, and those with large vessels are the most liable to suffer; such close grained timbers as beech and birch have not been observed to be attacked, and it is very probable that the size of their vessels is too small to allow of the insertion of a *Lyctus* egg. In so far as control measures are concerned, the Laboratory has concentrated its attention upon the practicability of heat sterilisation of infested timbers before practical utilisation. Humidity is an important factor to be taken into account, and there is evidence that prolonged treatment with humidity between 60 per cent and 70 per cent, provided the temperature does not fall below 120° F., would probably suffice for the purpose. The *Bulletin* may be obtained, price 3*s*. net, from H.M. Stationery Office or through any bookseller.

THORACIC APPENDAGES OF *ANOPHELES* LARVÆ.—The existence of peculiar paired dorso lateral organs on the anterior region of the thorax of *Anopheles* larvæ was described by Nuttall and Shipley in 1901, and confirmed by Imms six years later. On account of their transparency these structures are not easily seen, and this probably explains why they have been almost entirely overlooked by subsequent investigators. Mr. M. O. T. Iyengar, in the *Indian Journal of Medical Research*, vol. 16, No. 2, 1928, has studied these organs in 29 species of *Anopheles* besides examining many Culicine larvæ, but in the latter creatures the thoracic appendages were entirely wanting. Each appendage is capable of contraction and extension, and is moved by a special muscle. Morphologically the organ consists of a basal pedicle and two apical lobes, each of which is provided with a flat cuticular expansion. It is believed that the thoracic appendages, by maintaining close contact with the surface film, act as anchoring organs which maintain the larva in a constant position, and enable it to withstand the forward 'creep' while working its mouth brushes and thus setting up a current in the water. In the case of a Culicine larva, the movements of the mouth-brushes causes the animal to move in a forward direction all the time it is feeding.

NEW BIVALVES FROM SOUTH AMERICA.—In a paper entitled "New Freshwater and Marine Bivalve Shells from Brazil and Uruguay" (No. 2762, *Proceedings of the United States National Museum*, vol. 74, art. 17), Mr. William B. Marshall, assistant curator, Division of Mollusks, United States National Museum, describes a new pearly freshwater mussel from Brazil, four new freshwater mussels and three marine bivalves from Uruguay. *Diplodon Jacksoni* n. sp. is a handsome shell collected by Mr. Ralph W. Jackson of Cambridge, Md., from Arcas, Province of Mines, Geraes, Brazil. Its beak sculpture is usually well preserved and the whole shell measures 49 mm. by 28 mm. (type specimen). It is closely related to *Diplodon santamariæ*. The mussels from Uruguay are a Diplodon, two Anodontites and a Mycetopoda.

A Corbula and two Nuculas from Uruguay are also described One of the Nuculas, *Nucula Felipponei*, called after the donor, was taken from the stomach of a fish known as a corbina, *Micropogon undulatus* Photographic plates are given of all these new species

THE CULT OF THE PRIMULA —The first hundred pages of the *Journal of the Royal Horticultural Society*, vol 54, part I, 1929, are taken up with the report of the proceedings of the fourth Primula Conference, held under the auspices of the Society on Thursday, May 24, 1928, during the Chelsea Show The greater part of the space is occupied by the important paper by Prof W Wright Smith of Edinburgh and Mr G Forrest upon "The Sections of the Genus *Primula*" This paper has previously been published in the *Notes from the Royal Botanic Garden*, Edinburgh, No 76, March 1928 Accompanying this paper in its present, somewhat altered, form are a large number of beautiful photographic illustrations of various species of *Primula* Similar photographs accompany many of the other papers, which include some interesting notes on the Primulas of the Far East, especially a valuable discussion of their natural habitats in the East, by Dr W Handel Mazzetti, of the Natural History Museum, Vienna There are also valuable notes on cultural experience with difficult and rare species, whilst the workers at the John Innes Horticultural Institute are responsible for some interesting communications upon genetic experiments with *Primula* The late Dr Bateson commenced experiments upon the genetics of *P sinensis* so far back as 1903, these were continued by Mr Gregory and had yielded many valuable results before they were cut short by his untimely death in 1918 The three papers in the *Journal* upon *P sinensis*, *P Kewensis*, and *P Juliae* and its hybrids with the oxlip and primrose, are brief and clear summaries of the present state of our knowledge of the genetics of these species

JOLY'S THEORY OF THERMAL CYCLES —In a recent number of *Gerlands Beiträge z Geophysik* (vol 20, p 288, 1928), Prof J Joly replies to criticism by Dr F Lotze He points out that the theory of thermal cycles is more in keeping with the complexity of the earth's surface history than one of uniform loss of heat The suggestion of Dr J W Evans that radioactive energy may be in large part expended on chemical changes within the rocks dies hard Joly again directs attention to the fact that this suggestion is in flat contradiction with all investigations bearing on the subject He further claims, in opposition to Lotze, that volcanic heat liberated at the surface is negligible in quantity, and that it cannot be supposed to proceed in its entirety from the deep lying substratum which is responsible for the cycles. Perhaps the most interesting feature of this short paper is the tacit abandonment by Joly of the 'short' estimates of geological time, of which in recent years he has been by far the most ardent advocate On p 289 he asks, "To what other source than the theory of thermal cycles can we refer the repetitional character of earth history covering much more than a thousand million years?" Later, he states that "the surface history of the earth must have already run some thousand millions of years when the Appalachian Revolution took place" The momentum of the older view favouring a hundred-million year earth may now be said to have spent itself, leaving a clear field for the development of a geological time scale based on radioactive disintegration

DOMESTIC GRATES AND COKE —In a lecture delivered on Jan. 16 and printed in the *Journal of the Royal Society of Arts* for Feb 15, Prof C R Darling put before the Society what he considers a practical solution of the domestic smoke problem He has used, for two years, a grate for burning gas coke, in which the difficulty of ignition has been met by the incorporation of a gas burner This grate, introduced by the South Metropolitan Gas Company, seems satisfactory and economical, so that, taken in conjunction with other appliances and smokeless fuels available, Prof Darling considers that there is no technical obstacle to a large immediate reduction of domestic smoke This would follow the replacement of raw coal by gas coke and anthracite where possible, and so far as available Meanwhile the development of low temperature carbonisation processes will result in additional supplies of smokeless fuels to supplement the coke by the time demand for coke overtakes supply Technically, Prof Darling's claims are well founded The room heating efficiency of gas coke consumed in an open grate is greater than that of coal and at least as great as that of low temperature cokes The grate, however, must be accommodating to the peculiarities of coke, but the monetary saving following the use of coke will easily pay the cost of adaptation Unfortunately, in the matter of home heating, custom, prejudice, and æsthetic considerations often determine the choice, not technical efficiency Moreover until the ash content is brought much nearer to what is customary in house coal, it will be hard to secure the general adoption of coke in the open domestic fire

EFFECT OF ANTI KNOCK MATERIALS ON FLAME SPEED —The *Proceedings of the Imperial Academy of Science*, Tokyo, vol 4, No 9, contains a paper by Y Nagai on the speed of the initial uniform movement of the flame in hydrocarbon–air mixtures The effect of the addition of up to 25 per cent of diethyl selenide, tetramethyl tin, and tetramethyl lead to such mixtures was investigated in a long glass tube The flame speed, which was measured photographically, decreased with the concentration of the anti knock agent up to a certain point This effect is explained by a consideration of the differences between the theoretical propagation temperatures of the hydrocarbon (1450°) and diethyl selenide (1750°) and the tetramethyl compounds (both 1680°) It is suggested that the theoretical flame propagation temperature of the hydrocarbon is raised by addition of the anti knock compound until it reaches the corresponding temperature for that compound The maximum anti-knock effect is then obtained

AMATEUR KINEMATOGRAPHY —Dr C E K Mees has contributed an article to the January issue of the *Journal of the Franklin Institute* which includes an account of the Eastman Kodak Company's new Kodacolor process, which has been specially designed for the production of coloured films by amateurs In this, a colour filter with three separate areas—red, green, and blue—is used over the surface of the camera lens, and the film surface, instead of being flat, is embossed with small cylindrical lenses of the film material by forming it through steel rollers These lenses intercept the light directed on to the sensitive emulsion, which is at the back of the film, and so impress upon the latter three distinct sets of images, one for each of the primary colours of the filter The film is developed by a reversal process, and projected through an optical system which is essentially the same as that used for its production, the triple filter appropriate to the colour sensitivity of the emulsion being again placed over the lens A drawback of this method appears to be that there is considerable absorption of light by the colour filter used in projection,

with the result that only small pictures can be thrown on to the screen, but Dr. Mees states that although the Kodacolor process has been on the market for only a short time, the results that are being obtained show quite definitely that it is successful, and that with reasonable care there is no more difficulty now in obtaining motion pictures in colour than in the making of still photographs.

COSMIC RAYS.—The papers on cosmic rays that have appeared in Continental journals during the last three years have not hitherto led to any new results which have been generally accepted, and have not attracted much attention. Most of them have, however, included detailed reports of the observations which have been made, and have thus furnished a valuable collection of data for a statistical investigation, which has now been performed by A. Corlin, of Lund Astronomical Observatory, and published in the form of a *Communication* (No. 115) from this observatory in the *Zeitschrift für Physik* (vol. 50, p. 808). His analysis has brought to light a consistent variation in the intensity of the softer components of the radiation during the sidereal day. A maximum occurs at about 15h., a minimum at about 11 h., and a second, but less definite maximum, at about 7 h. The finer details of the intensity time curves of different investigators also show a certain degree of similarity. If soft rays are screened off from the ionisation chamber, temporal fluctuations are not present. The obvious inference is that the more penetrating cosmic rays are produced indifferently throughout space, but that at least a part of the softer radiation has a more localised origin. In a second *Communication* (No. 116) which has been published in the *Arkiv for Matematik Astronomi och Fysik* (vol. 21, No. 1) it is suggested that the softer rays are really initially hard, but that they are produced inside material celestial bodies and are softened by scattering on the way out. Further investigations are evidently needed to settle the important points that have been raised in these two papers and, as is pointed out, it would be extremely valuable if it could be arranged that simultaneous records of the ionisation produced by the cosmic rays were made at different latitudes.

THE PREVENTION OF IONISATION IN PAPER DIELECTRICS.—Messrs. S. G. Brown and P. A. Sporing read a paper on the prevention of ionisation in paper dielectrics to the Institution of Electrical Engineers on Mar. 14. It is known that the performance of paper dielectric condensers, which are much used in Great Britain in connexion with 600 volt alternating current systems, has not been satisfactory. After a period of service of about a year an appreciable number of breakdowns occur, and this takes place even when the condensers are subjected to very severe tests before installation. Very similar results have also been observed in connexion with cables insulated by impregnated paper. There is now a very large amount of evidence which supports the view that the breakdown is due to the presence of air bubbles in the dielectric. It is found that when the voltage applied to the cable or condenser is increased, then at a certain voltage, called the critical or ionisation voltage, the power taken by the cable suddenly begins to increase rapidly. The assumption is usually made that if the dielectric be worked below the critical voltages then ionisation of the enclosed air cannot take place. The authors show both by experiment and theory that this is not the case. They explain some of the phenomena observed by recalling the experimental results obtained by Lord Rayleigh and others on the electrical properties of thin layers of air. It is known that however close together two electrodes are in air at atmospheric pressure, then ionisation does not ensue unless the voltage exceeds a number which is approximately 330. They utilise this theorem in the design of condensers. Instead of increasing the thickness of the dielectric, they build it up of a large number of thin sections in series in such a way that the voltage across any one section does not exceed that required for ionisation. The same effect can be produced by placing isolated conducting layers (interleaves) in the dielectric. Great advantages are stated to accrue from this method of construction.

HYDRAZINE HYDRATE SOLUTIONS.—The concentration of hydrazine hydrate solutions, which usually contain less than 30 per cent. of available hydrazine, has hitherto been a matter of considerable difficulty, but a simple method of concentration is described by Hurd and Bennett in the *Journal of the American Chemical Society* for January. The hydrazine hydrate is mixed with a quantity of xylene and heated until the xylene has distilled away. The amount of xylene used determines the concentration of the residual hydrazine hydrate solution, and solutions containing up to 95 per cent. hydrazine hydrate can be prepared in good yield at one distillation. The aqueous portion of the distillate contains a small quantity of hydrazine which may be recovered. Toluene may be used in place of xylene, but is less efficient; benzene is quite unsatisfactory. Attempts were made to prepare hydrazine by treating its salts with sodamide, calcium carbide and aluminium carbide. With the two latter substances the desired reaction did not proceed, while sodamide reacted explosively unless diluted. The use of hydrocarbons as reaction media caused the reaction to proceed less violently, but only negligible yields of anhydrous hydrazine were obtained.

ARTIFICIAL ANALOGUE OF RUBBER.—The investigation of the problem of the chemistry of rubber by Staudinger and his school has been complicated in the past, on the natural side by the very great susceptibility of caoutchouc to oxidation, and on the synthetic side by the fact that the synthetic caoutchouc produced by condensation of the hydrocarbon isoprene may have a very different structure from the natural material owing to the possibility of molecules uniting together into complex three-dimensional systems. A new approach to the subject is described by Prof. Staudinger in the January *Berichte* (vol. 62, pp. 241-263). Instead of isoprene, the aromatic compound styrene is condensed. This, being a benzene derivative, cannot furnish a true caoutchouc, but the condensed product which it gives, *polystyrene*, may be regarded as a 'model' of the natural substance and can be accurately investigated, since its constituent groups can link together only in one single chain. An interesting discovery is that if the condensation is carried out at high temperatures, for example, 240° C., the product is relatively simple, being composed of some thirty units, whereas if the styrene is condensed slowly at ordinary temperatures it yields a very complex, colloidal substance, composed of some hundred thousand units, and resembling natural caoutchouc. All intermediate degrees of complexity are obtainable by varying the temperature and the time of condensation, and at any temperature the product obtained is a complex mixture of numerous members of a series, comparable with the series of natural paraffins; the most highly condensed products, and these only, resemble caoutchouc in viscosity, and in elastic and swelling properties. Prof. Staudinger concludes that natural caoutchouc is built up on a similar plan to polystyrene, and that it contains long chains of some thousand molecules of the unit 'polyprene,' $[C_5H_8]_x$.

Gravity Expedition of the U S Navy

By Dr F A VENING MEINESZ

IN the course of 1928 an invitation from the Carnegie Institution of Washington was received and accepted to go to the U S A with the apparatus for maritime gravity survey of the Netherlands Geodetic Commission The U S Navy, having received a communication on this subject from the International Union of Geodesy and Geophysics, wished to organise an expedition for determining gravity in the Gulf of Mexico and the Caribbean Sea The Secretary of the Navy, the Hon Curtis D Wilbur, designated the Naval Observatory for making the arrangements

The expedition took place in the autumn of 1928 It consisted of the U S Submarine *S 21*, on board of which the observations were made, and two surface ships, the U S *Eagles 35* and *58* The expedition was under the command of Lieutenant T L Nash, Captain of the U S *Eagle 35*, while Lieutenant J L Fisher had command of the U S S *S 21*, officers of the submarine were Lieuts F S Hall, F D Hamblin, and A R Sodergren The scientific staff on board the *S 21* consisted of Dr Fred E Wright, of the Geophysical Laboratory of the Carnegie Institution, Mr Elmer B Collins, principal scientist of the Hydrographic Office of the U S Navy, and myself

The expedition started from Washington on Oct 2 and completed the following schedule

Leave			Arrive			Number of Observations
Oct	1	Washington	Oct.	2	Hampton Roads	0
Oct	4	Hampton Roads	Oct	8	Key West	3
Oct	10	Key West	Oct	14	Galveston	7
Oct.	19	Galveston	Oct.	23	West Key via Mississippi Delta	7
Oct	29	Key West	Nov	2	Guantanamo (Cuba) via Bartlett Deep	8
Nov	5	Guantanamo	Nov	9	St Thomas via Nares Deep	9
Nov	15	St Thomas	Nov	19	Guantanamo via Caribbean Sea	6
Nov	21	Guantanamo	Nov	27	Washington	5

In addition observations were made in all the harbours, of which Hampton Roads Guantanamo, San Juan (during trip from Guantanamo to St Thomas), and St Thomas, were gravity stations, which have not been occupied before The total number of new stations amounted therefore to 49

The pendulum apparatus was mounted in the central control room of the ship, this was a favourable spot for making the observations, as it is near the metacentre of the ship, so that the rolling and the pitching cause only small translations of the apparatus The apparatus is hung in gimbals, which makes it possible to work it even if the rolling or pitching is very great, a few observations have been made with a roll of 7° to both sides of the vertical, and with a slight modification of the gimbals it is hoped that in the future observations may be made with still larger angular movements In this way it was often possible to work at periscope depth During the return however, from Guantanamo to Washington the Atlantic was so rough near Cape Hatteras that the two observations which had been planned above the top and above the bottom of the continental slope could not be made, as the ship's movement at 100 feet depth exceeded the limit of 7°

The apparatus used has been constructed at the workshop of the Meteorological Institute at De Bilt (Holland) by the chief mechanic L M van Reet, begun in 1925, it received its final shape in the spring of 1928 by the rearrangement of the photographic recording apparatus It consists of a pendulum apparatus and a recording apparatus, combined in one unit hung in gimbals

The pendulum apparatus contains three half second pendulums swinging in the same plane, in order to avoid magnetic influences brass pendulums are used, although of course their temperature constants are great An insulating cover reduces the changes of temperature inside the apparatus As however, the central control room of the U S S *S 21* showed less variation of temperature than the control rooms of the submarines with which I made previous voyages the temperature inside the apparatus was likewise more stable it seldom showed greater fluctuations than a few hundredths of a degree

The pendulums are not recorded separately but combined in two pairs For each pair the difference of the angles of elongation is recorded and this angle may be considered as the angle of elongation of a fictitious pendulum of the same period as the original pendulums It can be shown— and this is the fundamental principle of this method for determining gravity at sea — that the movement of this fictitious pendulum is free from the principal disturbing effect of the ship s movements the effect of the horizontal accelerations The records of the two pairs which the apparatus provides are therefore nearly regular, there remain only small disturbances by the vertical accelerations of the apparatus and by the tilt of the swinging plane The first is practically eliminated by taking the mean pendulum period over a sufficiently long period of observation for this purpose half an hour is more than enough The second makes it necessary to apply a certain correction to the result which can easily be computed if the tilt is known The apparatus is therefore provided with an auxiliary pendulum which can move in a plane perpendicular to the swinging plane and is damped in order to prevent its proper oscillations The position of this pendulum with regard to the apparatus is recorded This correction amounts only to a few units in the seventh decimal place of the second if the tilt is small for example not more than 10 , the gimbal suspension easily keeps it below this limit

Besides the records which have been mentioned, two others are made one of the temperature inside the apparatus and another of the middle pendulum alone This last record is necessary for computing the reduction of the pendulum periods to infinitely small amplitudes it is irregular because the movement of each pendulum is strongly disturbed, but as it is only used for the computation of a small reduction, this gives no special difficulties for the computations

The records are provided with two series of time marks by means of two shutters, which are actuated by electrical circuits opened and shut by two chronometers Each shutter passes during a fraction of a second before the light source which is used for recording purposes

The rate of these chronometers is found by taking wireless time signals, during the recent voyage the signals of Annapolis were used Reception was effected by means of an auxiliary chronometer, provided by the Naval Observatory at Washington, the rate of which had been strongly deranged, so that every 65 seconds a full second coincidence could be observed with the signals, of which the rhythm is the same as of mean time These coincidences were observed by ear through the well known method of putting the contact of this chronometer in series with the telephone of the wireless The appearances and the disappearances of the signals in the telephone have both been used

The rates of the chronometers have been satisfactory, so that the uncertainty resulting from the fact

that the rate during the observation may deviate from the mean rate deduced from the time signals will probably not amount to more than 2 or 3 millidynes in the result for the gravity

The programme of the expedition was chosen with an eye to the numerous geophysical and geological problems in that part of the earth s crust We may mention the question if isostasy prevails in the Gulf of Mexico in general and near or above the Mississippi delta, further, the problem of the Bartlett Deep south of East Cuba and the Nares Deep north of Porto Rico, the question of isostasy in the Caribbean Sea and in the Atlantic between Cape Hatteras and the West Indies, and lastly, the gravity field above the continental slope for that part of the coast of North America

Thanks to the whole hearted co operation of Captain Fisher, who ordered all the dives necessary for the measurements, this programme was fully accomplished This involved a great deal of diving, often several times a day—once even five times in seventeen hours—which meant an additional strain for every body The helpful assistance of the captain, officers, and crew during the whole voyage in all circumstances may here be thankfully acknowledged

Besides the pendulum observations a great number of soundings were taken The submarine was provided with the sonic depth finder of the U S Navy which has given excellent results, not only during submergence, but also at the surface soundings were possible so that the whole route could be covered Over the ocean deeps the soundings were taken at short intervals so that a detailed profile could be obtained

The results of the gravity observations were provisionally computed during the voyage, and at the same time the isostatic reductions of the stations were made at the bureau of the U S Coast and Geodetic Survey so that the complete provisional results were available a few days after the return of the expedition The final computations are now being made at the Naval Observatory at Washington Pending these a definite interpretation is not advisable but a few remarks concerning the provisional results may be given It is not probable that the final results will change these conclusions [1]

The Gulf of Mexico has shown a curious positive anomaly of about 60 millidynes over nearly its whole extent, only north of Yucatan it is somewhat less but the anomaly is still positive Towards Key West and Galveston this anomaly disappears Returning from Galveston to Key West a special series of observations was made over the Mississippi delta in two profiles perpendicular to the contour lines of the sea bottom, in order to investigate the isostatic equilibrium of the earth s crust in that neighbourhood It might be thought likely that deviations of equilibrium would occur because of the great load of material deposited by the river in the Gulf, but the results have not given any evidence in this direction The slight positive anomaly which has been found seems rather to be in accordance with the general trend of anomalies in the Gulf, so that there is no reason to bring them in connexion with the delta and to assume a lag in the re establishment of equilibrium

A second result of importance has been found over the Nares Deep, north of Porto Rico It is in harmony with the few values observed in that part during my former cruise with the Dutch submarine *K XIII* from Holland via Panama to Java It shows great departures from isostatic equilibrium, which probably may be ascribed to stresses working in the earth's crust in connexion with the formation of the deep Over the deep is a great deficiency of gravity, before reduction, it was more than 300 millidynes, and after isostatic reduction about 190 millidynes North and south of the deep the anomaly after isostatic reduction is small, north of the deep it is slightly positive (± 25 millidynes), and south of it on the north coast of Porto Rico slightly negative (- 10 m d) The gravity in Porto Rico is yet unknown, but the U S Coast and Geodetic Survey is planning an expedition for supplying a series of land values in connexion with the results of the expedition, and a few stations on the island will be occupied so that in a short time the continuation of the gravity field through Porto Rico will be known The importance of this land gravity expedition is obvious, it will complete the data which have been found South of the island, positive anomalies of about 40 m d have been found, as has also been the case throughout the whole part of the Caribbean Sea which has been crossed Summing up these results, we see that apparently the great deficiency of gravity above the deep is not accompanied by considerable positive anomalies in the neighbourhood, unless the values on Porto Rico should reveal any such anomalies

Another result worth mentioning in connexion with the deep is that two stations north of the island of Haiti both situated to the west of the Nares Deep, likewise show great negative anomalies (± 120 m d), and even farther to the west, in two stations north of East Cuba, the anomaly is still negative (± - 40 m d) This seems to indicate that the stresses in the earth s crust which are causing the Nares Deep are not limited to the region of the deep itself, but continue much farther to the west The topography itself does not reveal this

The values of gravity found above the eastern part of the Bartlett Deep, south of East Cuba, show smaller anomalies after isostatic reduction than the Nares Deep the greatest negative anomaly above the deep is 61 m d, while most of the anomalies found to the north or the south of the deep are less than + 25 m d This gives the impression that the stresses in this part of the crust are smaller than those near Porto Rico

Lastly, we will mention the results found in the Atlantic Ocean on the way back from Guantanamo to Washington The three stations above deep water, which are all situated near the bottom of the continental slope show small positive anomalies of about + 10 m d which contrast with the value of - 26 m d in Crooked Island Passage at the top of the slope and with the values found along the part of the Atlantic Coast to the south west of Cape Hatteras by the U S Coast and Geodetic Survey, which are likewise negative, their mean value is - 24 m d We find here an analogous result although somewhat less pronounced, to that found in 1926 by the *K XIII* on the west coast of Central and North America between Panama and San Francisco In the latter case the values above the top of the slope were about normal and those above the foot positive, with a mean value of about 65 m d, the difference between the values above the top and the foot of the slope has the same sign, but is larger on the west coast than on the east coast

Without wishing to enter into a premature interpretation of these results, we may mention two points First, it seems difficult to explain these isostatic anomalies by a different location of the compensation masses from that assumed for the isostatic reduction, so that we appear to be forced to accept a deviation of equilibrium on these coasts Secondly, an explanation of these disturbances of equilibrium on the west

[1] All the anomalies mentioned in this paper have been derived from gravity values which are isostatically reduced according to the method of the U S Coast and Geodetic Survey

coast by a westward drift of the American continent and a corresponding pressure on the ocean floor, seems not in harmony with the results which have now been found on the east coast, in this case the reverse might be expected — a negative anomaly above the foot of the continental slope behind the moving continent

Before and after the expedition, base observations were made with the apparatus both in the gravity base station, Washington, of the U S Coast and Geodetic Survey, and in the Netherlands gravity base station, De Bilt These observations provide, therefore, a new check on the comparison of Washington with the international base station Potsdam The final computations and the application of the final corrections of the time signals have to be awaited before any conclusions will be possible

The expedition has doubtless meant an important step for geodetic and geophysical science because of the immediate results of which a short sketch has been given in this article, but still more because of future possibilities should the U S Navy continue this research Results of great importance and extent might then be expected The expedition has been made possible by the co operation of the U S Navy with the Carnegie Institution and the Dutch Geodetic Commission Sincere thanks may be expressed to the Secretary of the U S Navy, the Hon Curtis D Wilbur, to Admiral Hughes, Chief of Naval Operations, to Admiral Leigh, Chief of the Bureau of Navigation, also to Captain Freeman, Superintendent of the Naval Observatory, for his indefatigable work in preparing the expedition

Personally, I wish to acknowledge the kind reception accorded me everywhere, in Washington, in naval as well as in scientific circles, on board the U S S *S 21* and the other ships, and ashore in the different ports which have been touched, where the naval authorities or, in St Thomas, the Governor of the Virgin Islands, gave me a most cordial welcome

Zoological Exploration of Mongolia

IN the summer, 1928, the Russian Academy of Sciences sent a zoological expedition to Mongolia, under the direction of A Y Tougarinov, who gives a short preliminary account of it in *Priroda*, No 12, 1928 The problem of the expedition was the study of the Mongolian fauna to the east of Urga, a region which so far had not been zoologically investigated The expedition took the route south-east of Urga Plains, with occasional chains of comparatively low mountains, or individual peaks, distinguished by extreme poverty and uniformity of fauna, stretch east of Urga practically to Hingan

The expedition was astonished by the great numbers of *Microtus brandti*, whose colonies stretch for tens of kilometres There are no large mammals, with the exception of rare antelopes, at times colonies of tarbagans were met The characteristic birds are *Haliaeetus leucoryphus*, *Buteo hemilasius*, and the desert larks Such poor landscape stretches up to Hingan, and only after 50 kilometres is a change observed Owing to the humid conditions, the semi desert is gradually transformed into a steppe, the herbaceous carpet is thicker, gramineous plants and other densely leaved steppe grasses are predominant A grassy steppe takes the place of the xerophytic flora. The representatives of desert, such as the sandgrouse, disappear, and dwellers of steppe and forest begin to appear, which shelter in the elm forests of the valley of Chalhin gol Representatives of Manchurian fauna such as *Xanthopygia tricolor*, *Pica sericea*, *Circus melanoleucus* are met with The expedition observed a great flight of birds across Chalhin gol, the species being characteristic of taiga and the tundra of eastern Siberia It may be assumed that here around Mongolia and along Hingan lies the migratory route of east Siberian birds, the origin of which is known to have been in the south east of Asia

Summing up the character of the explored region, it may be said that besides the Mongolian and Manchurian provinces mentioned, the rest of eastern Mongolia may be considered as one district, the chief characteristic of which is the predominance of central Asiatic fauna Series of species characteristic and usual to regions south of Urga are absent (for example, *Podoces hendersoni*, *Accentor fulvescens*, *Emberiza godlewskii*) Their absence cannot always be explained by the lack of suitable habitats The Turanian elements and the forms of the southern Palaearctic are also absent All this leads to the conclusion that recently the country has been exposed to conditions which have impoverished the fauna and hindered the spreading of forms from east and south The extreme desert state and the xerothermic climate were probably the required conditions

University and Educational Intelligence

CAMBRIDGE —Dr N E Goldsworthy, of Clare College, has been elected to the John Lucas Walker studentship for three years This studentship was founded for the furtherance of original research in pathology and is of the value of £300 a year for three years

Smith's prizes have been awarded to H D Ursell, of Clare College and J M Whittaker, of Trinity College Rayleigh prizes have been awarded to J Hargreaves, of Clare College, J G Semple, of St John's College, and S Verblunsky, of Magdalene College

EDINBURGH —At the meeting of the Senatus held on Mar 14, it was announced that His Royal Highness Prince George has consented to visit the University on May 15 to open the new Department of Zoology

At the same meeting the Senatus resolved to offer the honorary degree of doctor of laws to the following among others Prof E S Goodrich, Linacre professor of zoology and comparative anatomy, University of Oxford Prof A V Hill Foulerton research professor of the Royal Society, Prof C E Inglis, professor of mechanics and applied mechanics, University of Cambridge Dr A P Laurie, formerly principal of Heriot Watt College, Sir James Walker, emeritus professor of chemistry of the University of Edinburgh, and the Right Hon Baron Woolavington of Lavington

MANCHESTER —Sir Ronald Ross, Director in Chief of the Ross Institute and Hospital for Tropical Diseases, the discoverer of the life history of malaria parasites in mosquitoes, is among those on whom it is proposed to confer the honorary degree of D Sc on May 15

ST ANDREWS —H R H The Duchess of York has signified her willingness to be present at the opening on June 28 of the Graduation Hall gifted to the University of St Andrews by James Younger, of Mount Melville, St Andrews, and Mrs Younger After performing the opening ceremony, Her Royal Highness will receive the honorary degree of doctor of laws

Prof C E Weatherburn, of Canterbury College, Christchurch, New Zealand, has been appointed to the chair of mathematics in the University of Western Australia.

Applications from medical women are invited for the William Gibson research scholarship, value £292 per annum, and tenable for two years The applications should reach the Secretary, Royal Society of Medicine, 1 Wimpole Street, W 1, by June 1 at latest

The sixth vacation course in terrestrial and aerial photogrammetry will be held at the Technical Physical Institute of the University of Jena on April 8–20 Practical work will be arranged in connexion with the lectures, the necessary apparatus being provided by Messrs Carl Zeiss Particulars can be obtained from A Kramer, Schutzenstr 72 Jena

An election to Beit fellowships for scientific research will take place in July next The latest date for the receipt of applications is April 16 Forms of application and all information respecting the fellowships are obtainable by letter from the Rector, Imperial College of Science and Technology, South Kensington, S W 7

The Board of Education is again prepared to receive applications for full time studentships from teachers of not less than five years' standing, desiring financial assistance in order to attend approved full time courses of advanced study at universities or other institutions at home or abroad The amount of grant will not exceed £100 for an academic year The Board is also prepared to consider proposals involving travel or the practical study of industrial conditions connected with the teaching of technical subjects Applications for the year 1929–30 should be made as soon as possible Further information can be obtained from the Board of Education, Whitehall, London, S W 1

A scientific survey of secondary education in England and the United States has been initiated by the Division of Secondary Education of the University of Pennsylvania with the co operation of committees in both countries The English committee, of which Dr Cyril Norwood (Harrow) is chairman and Mr C W Bailey (Holt School, Liverpool), secretary, met on Mar 9, and in the light of information given by Prof E D Grizzell, of Pennsylvania, who is spending the year in England and has already accomplished much preliminary work, approved a scheme based on the selection of some fifty representative schools Many of the problems confronting secondary education to day are common to both countries, and this joint inquiry should prove helpful The rapid growth since the War in the numbers of schools and pupils has been accompanied by the creation of new types of school and modifications of the old to meet changed conditions, and there has been an enormous amount of research and experimentation in this field, of which the joint survey will doubtless take cognisance Of special interest at the present time are the numerous important researches recently conducted under the auspices of the Iowa Research Conference on Commercial Education, the survey of secondary commercial education in Minnesota and other studies, described in the report for 1927–28 of the United States Commissioner of Education, designed to contribute to improvement of instruction in commercial departments of secondary, normal, and collegiate schools

Calendar of Patent Records

March 24, 1802 —To Richard Trevithick, one of the greatest of British engineers and inventors, we owe the introduction of the high pressure steam engine, a patent for which was granted to him, in conjunction with Andrew Vivian, on Mar 24, 1802 The specification describes also a steam carriage to which at that time Trevithick attached considerable importance though he abandoned it after a few years of not very successful experiment The first locomotive to run on a railway was, however, the outcome of these experiments This was constructed by Trevithick, and ran at the Pen y darren Iron Works near Merthyr Tydfil for a few months in 1804

March 25, 1840 —The commercial success of electro silver plating was founded on the patent granted to George Richard Elkington and Henry Elkington, of Birmingham, on Mar 25, 1840 The idea of using the double cyanide of silver and potassium was due to John Wright, a Birmingham surgeon, who had been working independently in the same field, and, arriving in London to secure patent rights for his process, met George Elkington, then engaged on the preparation of his patent specification The two agreed to work together, and on the satisfactory demonstration of Wright s process, this was incorporated into the Elkingtons' specification

March 27, 1886 —The first commercial process to utilise successfully the action of diastase on starch in breadmaking was employed in the making of 'Bermaline' bread, under a patent which was granted to John Montgomerie of Lanark on Mar 27, 1886

March 28, 1764 —A step was taken towards the machine production of lace by the patent granted to Thomas Morris and others on Mar 28, 1764, for a new machine which is to be fixed to a stocking frame for making oilett holes or network in silk, thread, cotton, or worsted, as mitts, gloves, hoods, aprons, handkerchiefs, and other goods manufactured on stocking frames" The idea of the new machine seems first to have occurred to a stocking maker of Mansfield named Butterworth, who, with the object of having a machine made, confided it to John Betts, a smith Betts, however, obtaining financial support from Thomas and John Morris, hosiers, of Nottingham, took the invention to London, where the patent was granted in the joint names of the Morrises and Betts The patent was afterwards assigned to John Morris, and the invention was successfully applied in Nottingham, the knitting industry of which reaped considerable benefit from its introduction

March 28, 1787 —During the last few years of the eighteenth century, many experiments were made in England, America, and France in the application of the steam engine to navigation Amongst these, and the first to receive a practical trial in the United States, was the invention of John Fitch, who was granted a patent by special Act of Assembly for the State of Pennsylvania on Mar 28, 1787 A steam-boat, according to Fitch s specification, moved by twelve oars or paddles working perpendicularly after the manner of the paddle of a canoe, six paddles entering the water as the remaining six are raised, was built in Philadelphia, and ran on the River Delaware in 1788 carrying more than thirty persons a distance of 20 miles in 3 hours 10 minutes

March 28, 1907 —The control pillar or 'joy stick' in almost universal use in aeroplanes was the invention of Robert Esnault Pelterie, who was granted a French patent on Mar 28, 1907, in which an aeroplane with warping wings and elevators controlled by one lever was for the first time described A corresponding English patent was applied for in January 1908

Societies and Academies

LONDON

Institute of Metals, Mar 13 —**P Saldau** Special properties of eutectics and eutectoid alloys in binary metallic systems As regards hardness and electrical resistance, the eutectic occupies an abnormal position on the property composition curve, even in drastically annealed alloys For coalescence to occur, an excess of one of the phases is necessary —**F Hargreaves** and **R J Hills** Work softening and a theory of inter crystalline cohesion For work softening there must be more than one phase present and, roughly, *both* constituents must undergo spontaneous annealing after working at air temperature A theory of inter crystalline cohesion is outlined Briefly, it postulates the existence of a transition zone between two orientations Work hardening and work softening are identical phenomena concerning the early stages of the latter The pronounced softening caused by heavy working is attributed to interphase boundary action and the retention of the individual phases in a quasi viscous condition —**P J Durrant** The *constitution of the cadmium rich alloys of the system cadmium gold* The constitution of the alloys of cadmium and gold from 0 to 48 atoms per cent of gold has been reinvestigated by thermal and micro graphic analysis Saldau's equilibrium diagram, published in 1915, has been modified A new area of solid solution has been detected (phase III) which lies in the field described by Saldau as containing $\beta + \gamma$ This solid solution undergoes two polymorphic changes—one at about 500° C, and the other at about 375° C, the latter being analogous to the change in the β phase of brass at 460° C No evidence was obtained for the existence of the compound $AuCd_3$ at the liquidus, but the form of the equilibrium diagram suggests the existence of two compounds, Au_2Cd_5 and Au_4Cd_3, both of which are much dissociated at high temperatures —**Marie L V Gayler** and **G D Preston** The age hardening of some aluminium alloys Five typical aluminium alloys containing copper, magnesium silicide, or both, have been examined Changes in density and lattice parameter which take place during ageing suggest that precipitation from solid solution takes place X ray analysis shows also that the crystals themselves are in a disturbed state, which is gradually relieved by further ageing at high temperatures The increase in electrical resistance on ageing corresponds to this distortion of the space lattice of the solid solution, caused by the presence of minute particles due to the decomposition of the solid solution — **Clement Blazey** Brittleness in arsenical copper (2) Under certain conditions, about 0 004 per cent of bismuth can produce a susceptibility to brittleness The conditions are plain melting under charcoal of arsenical copper of the quality used, followed by poling and the addition of bismuth before casting The addition of phosphorus after bismuth destroys the susceptibility or it may be removed by remelting —**W Hume-Rothery** and **E O Rounsefell** The system magnesium zinc The equilibrium diagram of the system magnesium zinc has been investigated in the range 0 to 70 atomic per cent magnesium Particular attention has been paid to the structure of the solid alloys and the limits of solid solution in the various phases The compound $MgZn_2$, discovered by Chadwick, and $MgZn_5$, discovered by Grube, have been confirmed A new compound, $MgZn$, has been shown to exist, and this also is of fixed composition It may be distinguished from $MgZn_2$ by means of Benedicks' reagent The compound is formed at 354° C by a peritectic reaction between $MgZn_2$ and liquid On the practical side, the present work shows that in elektron metal, and similar alloys, any zinc present in excess of that contained in solid solution in magnesium will exist in the form of the new compound MgZn, and not, as previously supposed, as $MgZn_2$

Geological Society, Feb 20 —**C A Matley** The basal complex of Jamaica, with special reference to the Kingston district With petrological notes by **F Higham** There is a basal complex of great thickness, unconformably underlying Upper Cretaceous and Eocene rocks The 'granite and syenite' of the Survey—chiefly a granodiorite—is an important plutonic member of the complex, and contributes abundant pebbles to overlying Upper Cretaceous and Eocene conglomerates Another plutonic member of the complex is a peridotite of Harzburg type, now converted to serpentine The other members of the complex, many of which are found in a metamorphic condition, were originally sediments and volcanic lavas and tuffs The metamorphism appears to be late Palæozoic (Hercynian) or even older No trace of fossils has been found in the complex Comparison is made with similar rocks in Cuba, Hispaniola (Haiti and Santo Domingo) Porto Rico, and the Virgin Islands With the exception of Porto Rico, Jamaica now falls into line, as regards the presence of a pre Cretaceous basement, with the other islands of the Greater Antilles, although there is still want of agreement as to the ages of the rocks of that basement

Physical Society, Mar 8 —**Ezer Griffiths** and **J H Awbery** The dependence of the mobility of ions in air on the relative humidity The apparatus employed was a modification of Zeleny's original method, the end of a wind channel being closed by a disc of gauze fitted with a guard ring through which a steady stream of air of definite humidity was pumped The motion of the negative ions due to the action of the air stream was balanced by a counter potential gradient, and the mobility deduced from the critical potential required to produce a balance

LEEDS

Philosophical and Literary Society, Feb 19 —**W P Milne** Three theorems on the cubic surface —**A O Allen** A simplified derivation of v Seidel's aberration formulæ —**W H George** X ray examination of insulin, edestin, and hæmoglobins Only the powder method could be applied **G W Brindley** Distribution of charge on the carbon atom The F curve calculated for the carbon atom model does not agree quantitatively with the experimental curve The disagreement is most noticeable for large values of $\sin \theta$ for which the theoretical curve is known with most certainty —**H M Dawson** and **G Claxton** The miscibility of phenol with aqueous solutions of electrolytes If S and C represent the molar concentrations of the phenol and the electrolyte in the aqueous phase, then for a wide range of C values the experimental results are accurately reproduced by the formula $S = S_0 C^{kc}$, where S_0 is the value of S for $c = 0$, and k is a constant which varies with the nature of the electrolyte The results suggest that the miscibility is not appreciably affected by the interionic forces which are associated with the presence of the salt —**C K Ingold** and **H Burton** The existence and stability of free radicals The basis of the theory is the principle of electronic exclusion, which is also regarded as the radical cause of tautomerism —**W H Pearsall** Form variation in *Ceratium Hirundinella* O F M Statistics as to its variation in size and form in Rostherne Mere support the view that the

population is composed of a single race of this species The form variation shows three phases, and an explanation of the changes in size is advanced, based on the differential rates of protoplasmic growth and cell wall formation —**R G S Hudson** On the lower carboniferous corals *Orionastræa* and its distribution in the north of England The northern forms, with the exception of those from the D_2 zone, belong to other groups than that of *Orionastræa phillipsi* or *O placenta* and have therefore been described as new species and a structural sequence established

PARIS

Academy of Sciences, Feb 11 —**G Charpy and L Jacque** The reduction of the sulphates of the alkaline earths in metallurgical operations From the experiments described it is concluded that although it may be true that in certain metallurgical operations barium sulphate does not introduce so much sulphur into the casting as calcium sulphate, this is not due to a difference in the chemical properties of the two sulphates but to certain physical peculiarities more especially the fusibility of the slag — **A Khintchine** The law of large numbers — **S Serghiesco** The number of roots common to several simultaneous equations **Charron** A curious gyroscopic phenomenon —**E Huguenard and A Magnan** An apparatus for the comparison of aerodynamical velocities round an aeroplane —**Dussaud** Apparatus for the blind — **A Auric** The ring of asteroids An examination of the distribution of the asteroids with respect to their distance from the sun leads to the conclusion that the asteroids do not constitute one homogeneous family but a mixture of two families differing in their origin and their constitution The study of the distribution of the eccentricities and the inclinations of the orbits leads to the same conclusion —**Thadée Banachiewicz** The ellipticity of the terrestrial equator —**Z Horàk** The wave equation of Schrödinger —**Vasilesco Karpen** The equations of state and thermodynamics Reply to some criticisms by M Verschaffelt **B Decaux** The measurement of very high radiotelegraphic frequencies by means of piezo electric quartz oscillators —**A Travers and Nouvel** The solubility of $Mg(OH)_2$ at high temperatures Special attention was given to the preparation of a pure magnesium hydroxide, and in the experiments at high temperatures glass vessels were replaced by copper flasks The solubility becomes inappreciable at 178° C — **Lespieau** A heterocyclic diacetylene derivative The interaction of the dimagnesium compound of acetylene on symmetrical dichlormethyl ether gives rise to a substance the properties of which are consistent with the formation of a ring compound with eight carbon atoms and two oxygen atoms in the ring —**L Blanchard** Some derivatives of cyclobutanol —**Henri Moureu** The tautomerism of the α diketones The two tautomeric forms of phenylbenzylglyoxal and of phenylanisyl glyoxal —**L Meunier and R Guyot** The absorbent properties of cellulose fibres after treatment with formol in acid solution —**J Savornin** The artesian hydrogeology, hydraulics, and thermodynamics of the eastern Sahara —**Ch Killian** The development and biology of *Ambrosinia Bassii* —**P J Shiwago** The chromosome complex of the chicken and turkey — **Jules Lefèvre** Bioenergetics and its new laboratory — **C Levaditi and P Lépine** Experimental herpetic encephalitis of the ape

PRAGUE

Czech (Bohemian) Academy of Arts and Sciences (2nd class, Natural Sciences and Medicine), Jan 11 — **F E Vološin** A new ice pyrheliometer — **F Čechura** Magnetic declination in Bohemia in 1925 5 The following communications of members of the 2nd class of the Academy were presented to be incorporated in a jubilee volume in commemoration of the tenth anniversary of the foundation of the Czechoslovak Republic —1 **B Brauner** Some physiologico optical experiments — 2 **B Bydžovský** Symmetric involutions of the fifth order —3 **E Čech** Asymptotic correspondences between two surfaces —4 **K Domin** The hybrids and the garden forms of the genus *Pityrogramma* — 5 **J Hanuš, A Jílek, and J Lukas** Para brom benzol aceton its iso nitroso compound and dioxime —6 **J Hanuš and J Voříšek** The action of hydrazine hydrate on some unsaturated acids of the series $C_nH_{2n-2}O_2$, $C_nH_{2n-4}O_2$, $C_nH_{2n-6}O_2$ —7 **F Hasa** The quality of butt and molten electrical weldings — 8 **J Heyrovský and S Berezicky** The deposition of radium and other alkaline earth metals at the dropping mercury cathode —9 **I Honl-Ungarn** Properties of bacteriophages —10 **R Kettner and F Slavík** A new profile in Algonkian and Cambrian of Tejřovice — 11 **J Křepelka** A study of perselenic acid 12 **V Láska** Hyetometry in mountainous countries 13 **B Němec** Immunity in plants 14 **M Pelíšek** Space rolling of a hyperbola on a congruent hyperbola 15 **J Pelnář** The cancer of *Micterus* and our clinical experience —16 **K Petr** The composition of binary quadratic forms —17 **V Posejpal** Resonance spectra and the Raman effect — 18 **C Purkyně** The Carboniferous and Permian formations in western outskirts of Krkonoše (Giant's Mountains) —19 **V Rosický** Two articles on the study of crystal properties —20 **K Rychlík** The extension of the idea of congruence — 21 **J Štěrba-Böhm and S Škramovský** Complex oxalates of scandium —22 **V Trkal** The equation of the wave propagation in the wave mechanics and Hamilton s principle 23 **J Vilhelm** Verdant and proliferous flowers of some plants — 24 **E Votoček-V Prelog** The 3, 12 di hydroxy palmitic acid, a non sugar component of rhamno convolvulic acid —25 **K Weigner** Physical education respecting constitution and sex —26 **J Wenig** The structure of secondary envelopes of chords in *Ammocetes* —27 **J Wenig** A peculiar phenomenon in the abnormal growths of incisor teeth of Rodentia — 28 **F Záviška** The translation of circular cylinders through a viscous liquid

Feb 8 —**J Paroulek** The action of liver and ligamentic tissues on the exogenic uric acid —**J Scheiner** The lipoid nephrose —**V Jedlička** The pathogenesis and etiology of pernicious anæmia — **S Prát and Z Kobza** The chemical composition of some Algæ **J Babička** The Bohemian Travertins —**B Brauner** Analysis of water from the pond 'Babylon'

WASHINGTON, D C

National Academy of Sciences (*Proc*, Vol 14, No 12, Dec 15) —**Raymond Pearl, Charles P Winsor, and Florence Barclay White** The form of the growth curve of the canteloup (*Cucumis melo*) under field conditions The growth of seedlings of this plant in the field as in the laboratory, without exogenous food and light, can be represented by a generalised logistic curve The experiments suggest that, to a first approximation, the rate of growth is identical whether the environment is constant or highly varied, that is, it is determined by the organism itself Food from the soil, etc is only a means of prolonging its life — **E T Bell** Invariant sequences —**A Adrian Albert** (1) Normal division algebras satisfying mild assumptions —(2) The group of the rank equation of any normal division algebra —**Morgan Ward** Postulates for an abstract arithmetic —**Einar Hille and J. D**

Tamarkin (1) On the characteristic values of linear integral equations —(2) On the summability of Fourier series — **G A Miller** Groups involving a cyclic, a dicyclic, or a dihedral group as an invariant subgroup of prime index — **Ancel B Keys** The weight length relation in fishes It is shown statistically that this relation is given by {weight = constant × (length)^n}, where n is between 3 and 4 The form of a fish changes during growth, and the paper gives a method of calculating the magnitude of the change – **Gordon D Snell** A cross over between the genes for short ear and density in the house mouse The detection of one cross over shows that the genes for short ear and density, although borne in a common chromosome are not at identical loci — **Mildred S Moses** and **Chas W Metz** Evidence that the female is responsible for the sex ratio in *Sciara* (Diptera) Breeding shows that certain females are female producers and others male producers regardless of males with which they mate, fertilisation being by the first male used in mating —**Chas W Metz** and **Mildred S Moses** Observations on sex ratio determination in *Sciara* (Diptera) Sex ratio is probably determined by a simple Mendelian inheritance of a single pair of factors for which female producing females are heterozygous and male producing females and males are homozygous and recessive – **John Warren Williams** The relation between polarisation and association A development of Debye's theory that association in liquids depends on the interaction of the dipoles — **L W Elder, Jr**, and **W H Wright** pH measurement with glass electrode and vacuum tube potentiometer A quadrant electrometer is generally used with the glass electrode for electrometric work with substances affected by platinum A vacuum tube potentiometer gives consistent results and the only precaution necessary is that it must be set up in a dry atmosphere –**Carl Barus** Chemical reaction in the interferometer U gauge —**P W Bridgman** Resistance and thermo electric phenomena in metal crystals By an improved method of making single metal crystals, it has been possible to cast from the same melt a number of single crystal rods of a wide range of orientation The general results indicate that the Kelvin Voigt symmetry law for thermal e m f is an approximation The detailed paper is to appear in *Proc Am Acad Sci* **Ronald W Gurney** Angular distribution of intensity of resonance radiation It has been assumed that the emission of resonance radiation will be distributed at random in direction, this assumption seems to be unwarranted If the plane of polarisation of plane polarised light is rotated rapidly, consideration of the movement of the atomic oscillators shows that though the intensity along the beam is unaltered, in other directions it is modified This must be taken into account in intensity measurements of resonance radiation —**Stanley Smith** Some multiplets of singly ionised thallium – **J D Hanawalt** The influence of the presence of hydrogen on the L III X ray absorption edge of palladium Whether the hydrogen is occluded electrolytically or in a hydrogen furnace, there is X ray evidence of the presence of the chemical compound of formula Pd_2H, with a face centred cubic lattice in which alternate grating points are PdH molecules, the remaining points being occupied by Pd atoms —**Harlow Shapley** Studies of the galactic centre (3) The absolute magnitudes of long period variables – **B P Gerasimović** The absolute magnitudes of long period variable stars A period luminosity relation is obtained for a period of 100 250 days, mean absolute visual magnitude is −2 3, for a period of 250 340 days it is −1 1, and for a period greater than 340 days it is +0 3

Petrol

THE problem of petrol arises in acute form once again, and the lay mind is finding it difficult to reconcile continually increasing production of crude oil with, apparently, a directly proportional rise in price of its most valuable derivative As a purely economic consideration, petrol is not exactly a straightforward commodity to assess in terms of supply and demand, for the simple reason that this usually close relationship does not in this particular case express the condition of the oil industry at any time When complicated by conflicting commercial and political issues, these confined to no one country, it is small wonder that a number of the less obvious controlling factors in the situation fail to be appreciated by the public at large

From the technical aspect, the data of the problem are quite clear Of a total world production in 1928 of crude oil amounting to 182 million tons, the United States accounted for 127 millions, nearly 70 per cent, Venezuela, the next on the list, yielded 15 million tons, about 8 per cent, Russia contributed 11½ million tons, or about 6 per cent, Mexico, 6½ million tons, about 3 per cent and Persia, the oil industry of which figures especially prominently in contemporary discussions in the British press, produced 5 million tons, or 2½ per cent (the figures are approximate) Thus all the remaining countries combined account for only 10 per cent of the total output, and the United States persists as the dominating factor in the industry, so far as resources and exploitation are concerned Incidentally, in spite of local 'proration' agreements, that country continues to flood the market with some 385,000 tons of crude oil per day, a steadily rising figure Statistics can, of course, be made to prove practically any thing, but a sense of proportion born of a grasp of these data is the first step in understanding the present petrol situation

So many tons of crude oil output, however, do not constitute the barometer of the industry As E H Davenport has recently shown in a pamphlet entitled "The Price of Petrol" (London General Press), in order to appreciate the true economic position, the supply demand relationship of other important derivatives of crude oil must be ascertained, since petrol is only one of a series of vital products to modern civilisation

Now excluding paraffin and lubricants, fuel oil, a heavy residuum from crude oil distillation, has its own particular scheme of economics Apart

from its enhanced use as a basis of 'cracked' derivatives, it is essentially this oil of which we hear so much in competition with coal By no means an unimportant influence in the present petrol 'crisis' is this very item fuel oil, the market vicissitudes of which operate directly in response to fluctuations of coal supply and demand There is a great deal of nonsense written about the antagonistic purposes of oil and coal, but one thing is abundantly clear the two commodities, in so far as supply and demand are concerned, are as sensitively balanced in the world of fuel as any delicately poised beam in a laboratory

If for any reason fuel-oil receipts drop in favour of other forms of thermal energy, the deficit must be spread throughout the oil industry as a whole Since petrol is the most thriving product of all for which that industry is responsible, it must perforce shoulder its share—a lion's share at that—of the burden This means that the net profits on the sale of petrol tend to be lessened periodically by a fluctuating amount Since the oil companies with all their faults are at least financially sane, and realise better than anyone else what is the economic minimum at which petrol may be retailed to show a working profit *on the total cost of their complete operations*, not being philanthropists, they have perforce to pass on such fluctuations, either plus or minus, to the consumer, the latter is, after all, the only possible individual who can harmonise the contending factors But this is only one other aspect of the matter

Whatever may or may not be the wisdom of amalgamations or 'combines' as they have come to be known, monopoly, if this be implied and providing it be not abused, can operate in favour of the public by supplying standard commodities at standard or at least economic prices Any undercutting of such prices as may ensue, unless backed by resources constituting a serious menace to the major interests, will be local and short lived The public gains a penny here and there, but is soon forced back to acceptance of 'combine' prices, either through restricted operations of the external interests involved, or through ultimate failure of the latter to contest the market Should there be, however, a definite attempt at breaking monopoly by prolonged attack, supported by the formidable weapons of large resources of equally high quality products, then competition runs keenly and the public is undoubtedly the gainer during the phase of severe price-cutting which ensues

If during this period natural resources were for any reason to decline, a truce might automatically be called, but if, as is the actual case, resources increase at a rate which definitely establishes supply in excess of demand, then sooner or later the position has to be faced by the contending parties which, put briefly, means compromise or bankruptcy There must always be an economic limit, especially in petroleum undertakings, below which it pays no one to produce and distribute petrol, or any other commodity for that matter In the present circumstances, both competition, heavily backed by adequate resources, and over production have helped to bring about the logical situation now being faced by producer and consumer

The recent increase in price of petrol in Great Britain is not an impetuous act of economic or political spite Its incidence is a direct outcome of a chain of circumstances the operation of which has all along been perfectly clear to the intelligent observer who is not content to accept at face value *ex parte* statements in the daily press

The immediate post War price of petrol was, of course, excessive, but rendered inevitable by the difficult conditions of restabilisation of international trade, in which petroleum played no unimportant part This price, however, did not last long, for despite an enormously increased demand for petrol since 1920, supplies more than kept pace, due not so much to over production of crude oil, but, as Davenport points out, to the economic operation of 'cracking' in refinery process Thus, applied science has had a direct hand in price control, for perfection of cracking plants has led to considerably enhanced petrol yield per barrel of oil run to the stills, apart from influencing paraffin production, etc Hence the principal organisations responsible for producing and marketing petrol were able to take full advantage of public demand, and to hand on to the consumer a small share—in the shape of decreased price per gallon—of the success they were enjoying

Then came, as it was bound to do, the Russian entry into the market To understand the full significance of this incursion, it should be recognised that, apart from any commercial or political prejudice, petroleum emanating from the Russian fields is, technically speaking, of exceptionally high quality, a fact well known from the earliest days of the oil industry While this statement in no sense implies inferiority of competitive oils or products, the temporary exclusion of this fuel from European markets was something of a calamity Nothing but abundant resources and sound refining values could have re-established so quickly Russian oil in the world's markets, to the

extent of constituting that country the third most important producer last year Whatever may be the ethics of the case, there has been an undoubted demand for Russian oil in Great Britain during the last few years, a demand which, in its growth, has forced the very issue to which we have referred A measure of the economic situation created in 1928 is to be found in the price of petrol in London prior to Government tax 1s 0½d per gallon (ex pump) Anyone, even with the slightest knowledge of the technical side of the oil industry, knows that such a price is unsound and can never bear a proper ratio to capital outlay and cost of production, especially when it is remembered that from that figure transport charges and retailer's commission must be deducted before the producer can reckon his profit Consequently, things were destined to alter in any case, and compromise between conflicting interests was an inevitable policy foreseen long before the *fait accompli* was realised The natural corollary to such compromise is the raising of the price of petrol to an acceptable economic minimum

In the meantime, however, the Government made an imposition of 4*d* tax per gallon of petrol last year, to which the retailer added ½*d* as cost of collection Thus in London the price of petrol rose to 1*s* 4¾*d* ex pump, or 1*s* 5¾*d* (or more) in the provinces This, however, had nothing to do with the economic situation in the industry, though it may since have had some slight repercussion in the matter of decreased demand The price of petrol at the round figure of 1*s* 5*d* or 1*s* 6*d*, though possibly distasteful to the consumer, clearly left the main problem of economic minimum unaffected, and something was bound to happen to alter these conditions from the point of view of the well being of the industry as a whole The plain fact is that, until the recent increment of 2½*d* per gallon was made by the industry on Mar 1, nothing had occurred to alleviate the serious position of a year ago, the addition of this increment is an expression of compromise between contending interests, or, in the absence of any specific agreement at the moment, it is a measure of consolidation of the inevitable position which the industry must take up to 'put its own house in order' whatever may fall in the future Even now, it should be noted, the increase only brings the total price of petrol to 1*s* 2¾*d* per gallon excluding tax it remains to be seen for how long that price will be considered adequate to the needs of a complex industry

Petroleum, once exploited, is a wasting asset In the face of production on a scale never before achieved or even contemplated, it is difficult to forecast events, but anything which tends to promote its economic production and utilisation may be construed as a measure of conservation, and this care it is the duty of the industry to foster If enhanced price of petrol is economically justified, as we believe it to be, then it will have the effect of strengthening the industry in a determination to prevent waste of this valuable commodity at all costs To this extent recent events have perhaps been beneficial H B M

Practical Oceanography

Science of the Sea an Elementary Handbook of Practical Oceanography for Travellers, Sailors, and Yachtsmen Prepared by The Challenger Society for the Promotion of the Study of Oceanography Originally edited by Dr G Herbert Fowler Second edition, edited by Dr E J Allen Pp xxiii + 502 (Oxford Clarendon Press, London Oxford University Press, 1928) 15*s* net

THE Challenger Society has done well in issuing a new and revised edition of this well known and useful book, which has been out of-print for some years, and the new editor, Dr E J Allen, is to be congratulated on having retained the original character of the work, while bringing it abreast of modern progress Oceanography has advanced in several directions since the War, and its progress has been due in no small measure to British work, though we have had no great oceanographical expedition devoted purely to such problems, as the Germans have had in the *Meteor* expedition One would like to see Britain again taking the lead in great oceanographical explorations, as befits her position as the greatest seafaring nation Much of interest will no doubt come of the *Discovery* expedition, but this is necessarily tied down somewhat strictly to the investigation of the very pressing economic problems arising out of the exploitation of whaling May the "Science of the Sea" help in stimulating that interest in the problems of the ocean which is dormant in the heart of every Briton, and bring the time nearer when the purse strings will be loosened to enable Britain take her rightful part in oceanographical exploration

The book is addressed primarily to "travellers, sailors, and yachtsmen," to all those whom business or pleasure takes upon the great oceans, and it will prove of inestimable service to all such who wish

to take part, in however modest a fashion, in the study of marine problems To those who ask, "What can I do for oceanography?" this book supplies a sufficient and thoroughly practical answer It will be of interest also to others, to those who have no opportunity to do work at sea, but wish to learn about oceanographical problems and the methods by which they are studied Also, the student who is beginning to take up marine or fishery work will profit greatly by a careful reading of this book, which has the great advantage of being written throughout by practical workers of long experience and proved competence

As we have said, the volume follows fairly closely the arrangement adopted in the original edition, and certain sections show little change, though all have been revised The chapters on the air and water have been completely re written, the former by Capt Brunt and Comdr Garbett, the superintendents respectively of the Army and Navy Meteorological Services of the Air Ministry, the latter by Mr D J Matthews and Dr W R G Atkins Both chapters are extremely well done Dr Atkins's contribution deals with the alkalinity of sea water, and gives a full account—perhaps just a little difficult for the beginner—of the methods to be employed in determining the pH of sea water Mr Matthews describes in outline the main current systems of the oceans, and gives eminently practical instructions for the use of hydrographical instruments and methods It might have been well to mention Lumby's surface sampler which makes the collection of water samples from vessels under way much easier and more satisfactory than the old bucket method The definitive description of this instrument has, however, only just recently been published (*Jour du Conseil*, **3**, 3, 1928) An interesting comment is made by Matthews on the echo sounding method of determining depths He rightly fears that the spread of this most valuable method will result in a serious decrease in the number of bottom temperatures and samples of bottom deposits col lected

In the biological sections there is apparent a certain inequality of treatment—the fixed plants, for example, are dealt with in a very adequate manner by Mrs Weber van Bosse, while the fishes receive much less space But one must admit that to treat of the fishes in a comprehensive way would have taken up practically the whole volume The section on phytoplankton, by Dr Marie Lebour, is new, and, though short, is admirably done Prof Stanley Gardiner has re written his fascinating and practical account of tropical shore-collecting, and the section on fishing gear has been considerably strengthened Of great practical value is the chapter on the preservation of marine animals, by Dr Allen and Mr E T Browne—a subject on which expert advice is always welcome Prof D'Arcy Thompson's charmingly written account of whales and seals—and sea serpents—will be of especial value to the ocean traveller

The illustrations are on the whole good, with the exception of some of the small figures of plankton and benthonic animals The useful appendices of the original edition are retained and expanded—a list of marine stations, of literature, of recom mended firms for the supply of apparatus, and an outline biological classification The list of litera ture might have been extended with advantage One notes with interest and some surprise that the number of marine stations listed, in all parts of the world, amounts to more than one hundred The frontispiece is, most appropriately, a portrait of the late Sir John Murray, to whom the science of the sea owes so much

Colliery Economics

The Economics of Coal Mining By Prof Robert W Dron Pp vii + 168 (London Edward Arnold and Co, 1928) 10*s* 6*d* net

THE subject of the above work is one of the greatest possible importance at the present moment when coal mining problems bulk so largely in the public interest Prof Dron has produced a very readable and very useful little book in which most of the problems connected with the economics of coal mining are succinctly reviewed It comprises ten chapters namely, an introductory chapter, one devoted to mineral leases, two to valuations, the first of these referring to the valuation of a mineral property and the second to the valuation of an operating colliery, another chapter considers the economics of the development of a new undertaking another gives estimates of capital expenditure, another the cost of power production, whilst the final chapters are devoted to the organisation of a colliery, to coal cleaning, and to legal considerations, the latter being devoted mainly to the questions of subsidence and trespass

As might be expected from a colliery engineer of Prof Dron's knowledge and experience, the work is throughout of a high order, since, however, a large number of the questions treated of are of a distinctly controversial nature, few mining engineers

will be found to agree with all Prof Dron's views, though a large majority of them will agree with the greater portion thereof

When critically examined, the chapters on valuation are probably the weakest in the book, and give evidence of less clear thinking on this important subject than might perhaps have been expected from the author Thus, in the chapter dealing with the valuation of mineral properties, the author introduces a consideration of the costs of mining operations, such costs have, however, nothing at all to do with the case, because the value of a mineral property is determined solely by the consideration of the income which this property would yield and, therefore, the capitalised value of the mineral royalties In a previous chapter the author has considered the true meaning of royalty and quite correctly distinguishes between it and an occupation rent, and quotes the authoritative statement on the subject from the Report of the Royal Commission on the Coal Industry (1925), which shows that "a rent is paid for the use of a thing which endures," whilst "a mineral royalty is paid for the purchase of the thing itself"

Prof Dron is, however, in error when he considers that the word royalty is a survival from Queen Elizabeth's time The word was never used in this modern sense by medieval writers, and, in fact, its first use in this particular sense appears to date from the first half of the nineteenth century Prof Dron refers correctly enough to the decision about the year 1568, which assigned all mines except royal mines to the owners of the land in which they occur, but he omits to point out that the Crown never at any time even claimed the ownership of or a royalty in respect of coal The distinction is sufficiently important for Prof Dron to have directed attention to it It may also be suggested that the Scotch term 'lordship,' which is the Scotch equivalent of royalty, should not be used without defining it for English readers

Prof Dron has fallen into a curious arithmetical blunder in his footnote to p 31 in discussing the local rates payable by mineral owners in Scotland He states quite correctly that in Scotland the local rates on a colliery are payable approximately one half by the owner and one-half by the lessee, but goes on to say that in England and Wales, "so far as the writer is aware, no part of the local rates is paid by the mineral owner" Prof Dron's statement on the latter point should have been much more definite, and he appears to be unaware of the reason for this difference, in England and Wales the fixing of rates is based upon the well-known statute of Queen Elizabeth's time, which enacts that rates may be levied upon every occupier of coal mines, etc this statute has since been greatly extended and modified and other rates have been added, but the basal principle that the occupier is liable for the rates has never been altered

In Scotland, on the other hand, the fundamental legislation which controls rating is contained in an Act of Queen Victoria's time passed in 1854, and although the general principle laid down in that Act is varied to some extent by the local Acts, its general effect remains, so that approximately one half of the rates is paid by the owners of the mine and the other half by the occupiers The reason for the difference in treatment of mine owners in Scotland and England is thus quite clear

Prof Dron's error, which has been referred to above, is in his calculation of the amount of the local rates payable by mineral owners, which he states "is equal to about 1*s* 6*d* per ton of output" He bases this on his statement that the local rates payable by mineral owners in 1925 were about £230,000 per annum He has previously given the output for that year as 28,394,000 tons (a clerical error in the table on pp 10 and 11 would make this about 28,000 million tons, but this error does not affect the case) A simple calculation will show that the rate above given amounts not to 1*s* 6*d* per ton but to nearly 2*d* per ton, and it can only be surmised that Prof Dron has carelessly misplaced a decimal point Such an error is a comparatively venial one, but in the present instance would lead to important results Prof Dron has no doubt a long and varied experience in dealing with Scottish mineral owners, but it may gravely be doubted whether he has come across one so constituted as to be willing to accept 6*d* per ton in payment for his coal and pay out in return 1*s* 6*d* per ton for his rates Scotch mineral owners are not usually credited with such a degree of quixotic altruism or such utter carelessness to their own interests as a bargain on Prof Dron's lines would appear to indicate, and it is incomprehensible why this fact should not have struck him whilst he was writing the lines in question

It may also be asked what Prof Dron means by stating that his chapter on the valuation of minerals is devoted to the simplest case, namely, "the valuation of minerals in actual course of working," and a few lines further down to discuss such a valuation in the case "if the winding pits are not established on the property under investigation" It

would be interesting to know how the mine could be in the course of working before the winding pits are sunk

In his next chapter, on the valuation of a going colliery, Prof Dron commits an error into which very many, perhaps the majority, of mining engineers are apt to fall He tabulates for a valuation of a colliery the estimated future output and the life of the coalfield, in other words, he commences by stating what the quantity of coal is which the field in question contains This is a fact that neither he nor anyone else can know in advance, he might be entitled to state that the field is estimated to contain a certain quantity of coal, though the more correct statement would be that the most probable quantity of coal contained in the field is so much, the most probable quantity being that which is as likely to be exceeded as to be fallen short of when the coal comes to be actually worked Until it is worked, no one can say how much the field actually contains

Prof Dron deals very briefly with the problem of deferred royalties, and it seems evident that he has not seen the elaborate discussion of the subject in a paper on The Value of a Deferred Annuity, with Special Reference to the Valuation of a Mineral Property, by Charlton Carpmael (*Jour Inst Actuaries*, vol 56, pp 25 72 1925)

In conclusion, it may be said that the chapters here selected for detailed criticism are on a subject which is perhaps the most difficult and the most controversial of any in the book, and the fact that different views are here put forward on many points to those advanced by the author must not be taken as any indication that the book is not an exceedingly valuable one indeed, it is likely to be of the utmost use to all colliery engineers

British Sea Anemones

The British Sea Anemones By Dr T A Stephenson Vol 1 (Ray Society Volume No 113) Pp xiv + 148 + 14 plates (London Dulau and Co, Ltd, 1928)

WHILST in some branches of science, especially physics, there are so many workers in the field that monographs can be continually revised, in others many years must pass by before an expert can bring our knowledge up to date Dr T A Stephenson, one of the two leading workers on anemones at the present time, is to be congratulated on his effort to bring together and set in order the facts known about British sea anemones, their structure, development, bionomics, and classification It is the first successful attempt to supplement the famous work of Gosse completed so long ago as 1860, when the comparative anatomy of anemones had not been studied

It will perhaps be a disappointment to some who have looked forward to the appearance of this important work that the body of it is apparently being held back for a subsequent volume Although the author lays stress on the fact that for the purposes of the monograph a clear understanding of anatomy is necessary, it is doubtful whether the general reader will feel urged to read through the technical and well illustrated section on structure, which occupies the greater part of the text, until the appearance of the next volume this will presumably contain descriptions of the species But the remaining sections, particularly that on bionomics, are full of absorbing interest

The author describes the different haunts of these animals, and points out where the best collecting grounds are, and which species can best be maintained in aquaria Interesting notes are given of the rapid way in which some anemones can move about, of how they capture and digest their food, and, above all, of the various methods of reproduction, even at the mature age of three score years and ten He instances one anemone which, as soon as it begins to rove about, leaves behind pieces of its base, which, retaining hold of the substratum, regenerate into normal individuals True budding is not a characteristic of these animals, the total absence of colonialism and skeleton building being correlated with a relatively active habit Their ancestors were probably creeping, bilaterally symmetrical forms, and radial symmetry supervened when a more sedentary life was adopted

Dr Stephenson is an artist of no mean order, and has drawn a number of beautiful and convincing studies of living anemones He is careful to explain, however, that individuals can look quite unlike the portraits given of their particular species, and that his illustrations necessarily represent fleeting aspects of selected colour varieties of most changeable organisms He goes into the questions of coloration and pattern, and the methods of collecting and maintaining anemones in aquaria Notes are given on natural enemies and messmates The author mentions their use for fishermen s bait, and that they form a considerable part of the diet of some fish like cod, whiting, haddock, and especially flounders A long list of works on anemones is given, and the reader is shown where to look for information under various sub-headings

A K Totton.

Our Bookshelf

The Yearbook of the Universities of the Empire, 1929 Edited by T S Sterling Published for the Universities Bureau of the British Empire Pp xiv + 852 (London G Bell and Sons, Ltd, 1929) 7*s* 6*d* net

IN pre War days, "Minerva" was the standard reference book of the personnel of the universities and learned bodies of the world After a lean period, it has regained its position, but at the cost of growth to three very bulky volumes The "Universities Yearbook" covers the universities of the British Empire and is a compact handbook of less than a thousand pages, its data, being compiled from university calendars and similar official publications, is thus trustworthy

The "Yearbook" is divided into sections dealing with Great Britain and Ireland, Canada, Australia, South Africa, and India respectively Each section is preceded by a brief account of the history and the regulations of the universities of the section, after which each university is dealt with separately A directory of the staff, arranged under departments, is given, followed by general information, including equipment of laboratories, museums, etc, degrees, residential accommodation, changes of staff during the past year, student statistics, and so on

The appendices occupy about a third of the book and provide most valuable information, which is only available elsewhere in widely scattered publications They cover the regulations for professional bodies, matriculation examinations, inter university scholarships and grants for research, professional schools of the universities, and the distribution of subjects in which various universities specialise, centres of research outside the universities, and titles of theses accepted for research doctorates There are name and general indexes

We commend the book to all who wish for information on educational facilities of university standing For ourselves, there are few reference books to which we turn more frequently or with more confidence

The Symmetrical Optical System By Dr G C Steward (Cambridge Tracts in Mathematics and Mathematical Physics, No 25) Pp viii + 102 (Cambridge At the University Press, 1928) 7*s* 6*d* net

THIS is the latest addition to the useful series of Cambridge Tracts in Mathematics and Mathematical Physics It enlarges upon the short section devoted to the characteristic function in the earlier book of the same series ("The Elementary Theory of the Symmetrical Optical Instrument," by J G Leatham), by an early use of the functions of Hamilton and Bruns The author has made a welcome departure from the purely geometrical discussion in calculating the distribution of energy in diffraction patterns associated with the primary aberrations, a purpose for which treatments based upon the principle of optical path are naturally convenient It is to be hoped that the end of optics completely divorced from practice has at last arrived Had the developments made by the author and Mr T Smith been only a little earlier, the subject of geometrical optics might still have been included in the Tripos

It might be suggested that the heading of Chapter v, "The Computation of Optical Systems," is a little misleading The chapter deals with the computation of aberration of optical systems, and not with the design of systems, as the heading might lead one to suspect

The book is, of course, addressed only to readers with the requisite mathematical equipment Those without such an equipment can obtain many of the same results by other means

The Story of the American Indian By Prof Paul Radin Pp xiv + 371 + 30 plates (London John Murray, n d) 21*s* net

IN the story of the American Indian, Dr Radin traces the spread of offshoots of the elaborate Maya civilisation over a great part of North America There was, according to him, one stream of an early stage of Mayan culture that evidently went by sea to the mouth of the Mississippi, spread mainly northwards to found the culture of the Mound-builders, and underwent transformation as it proceeded, eventually these immigrants were overwhelmed by the simpler peoples around them Certain cultural traits spread over the plains, weakening as they reached the north eastern woodlands Another stream (of Toltec culture) flowed into Arizona and New Mexico, where it overlaid an older Mayan layer that had spread from the east, this culture was partially assimilated by the Navaho, Pawnee, and others The capitalists of the north west coast have closer affinities with Asia and striking resemblances to conditions met with in Melanesia The high pre Inca cultures of Peru are discussed in a similar way

Dr Radin traces these connexions in an interesting manner The book should not be overlooked by ethnologists, but being innocent of references and an index, it is apparently written for non specialist readers

Lehrbuch der anorganischen Chemie Von Karl A Hofmann Sechste Auflage Pp xv + 784 + 7 Tafeln (Braunschweig Friedr Vieweg und Sohn A G, 1928) 20 gold marks

THE sixth edition of Prof Hofmann's "Lehrbuch" follows the preceding edition after an interval of three and a half years No drastic alterations have been made, but an important chapter of twenty three pages has been added on the organo metallic compounds This is included in a part of the volume which contains chapters on explosives, structure of inorganic compounds, structure of crystals, radioactivity, and atomic structure Those who are not acquainted with the book may therefore be assured that it deals as adequately with general questions as it does with the properties of individual elements and compounds

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

Excitation of Mercury Vapour by the Resonance Line

THE early researches of R W Wood (1912) showed that mercury excited by the light of the line 2537 emitted resonance radiation of the same frequency as the absorbed light

Accompanying this resonance radiation there is radiation of longer wave length, comprised chiefly in two broad maxima, one about λ3300, and the other giving rise to visual green fluorescence These last radiations, which are regarded as of molecular origin, appear at higher vapour densities than are required for the resonance radiation, which has always been regarded as a purely atomic phenomenon

F S Phillips in 1913 showed that the visual luminosity could be caused to move away from the place of origin if the vapour was in rapid motion Photographing the spectrum, he concluded that the ultra violet radiation around λ3300 and the line 2537 could also be detected in the vapour stream away from the place of origin

I have always been puzzled by these phenomena, and the mystery has not seemed at all less since observing (see NATURE, Nov 10, 1928) that the visible radiation could be produced by excitation lower than the resonance line, and that in this case too the secondary source was capable of being blown away from the place of excitation

The question arises What is the relation between the 2537 radiation and the visual radiation in Phillips's experiment ?

Although not yet prepared with a complete answer, I wish to describe some experimental results which analyse the phenomenon more closely than has yet been done

The distillation may be carried out *in vacuo*, or with a moderate air pressure in the condenser, which results in a more dense but less rapid vapour stream The added air does not mix with the mercury vapour under these conditions until the condenser is reached

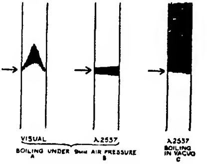

FIG 1

Distilling the vapour up a silica tube 1 5 cm square section, with an air pressure of 9 mm in the condenser, the visual glow is of the shape shown in Fig 1A, the arrow indicating the direction of the narrow incident beam The arched form indicates, as Wood and Pienkowski have shown, that after excitation there is a time lag before the luminosity sets in This is most apparent in the middle of the tube, where the stream is most rapid

On the other hand, the re emitted ultra violet radiation comes laterally from the cone marked out by the incident rays, undeflected by the vapour current (see Fig 1B) This appearance is obtained by photographing through filters of chlorine and bromine in series, which transmit the line 2537 but cut out the less refrangible radiations

Finally, on making the vapour current more rapid by completely exhausting the condenser, the visual radiation is thinned out to vanishing point, and the source of 2537 radiation moves up as well (see Fig 1C) That this really is the radiation 2537 was checked by photographing through chlorine and bromine with addition of mercury vapour in an independent cell, of such thickness and density as to absorb about a breadth of 1 A at this point without absorption at any other relevant part of the spectra The luminosity in the tube was altogether cut out by this filter

It seems therefore, so far as can be judged from the evidence yet available, that the 2537 radiation is simply Wood's resonance radiation, and that in the experiments with a blast of vapour its source can be observed as separated in space from the source of the continuous bands which are doubtless of molecular origin But if this interpretation is accepted, the surprising thing is that the source of resonance radiation is in itself capable of moving considerable distances in a sufficiently rapid blast This would show that the interval between excitation and emission is under some conditions enormously longer than the 10^{-7} seconds usually assigned If so, many received views will need revision

The Constitution of Oxygen

W F GIAUQUE and H L Johnston in a recent letter (NATURE, Mar 2, p 318) state that certain observations on absorption bands are only explicable by the hypothesis that oxygen contains atoms of mass 18 Unfortunately, they do not give any indication at all of the abundance of these relative to the normal atoms

So far as I am aware, there is no evidence obtained from positive ray analysis of any kind which would lead us to suppose oxygen other than a simple element In my recent measurement of packing fractions the line due to O^{16} was taken as standard and, to take the cases in which the evidence is most trustworthy, the atomic weights of hydrogen, fluorine, and iodine determined in this way were found to agree with the accepted values to within one part in ten thousand The latter are expressed in terms of the mean atomic weight of oxygen, so that this is very strong, though indirect, proof that if O^{18} exists it cannot be present even to the extent of one part in one thousand

In order to obtain evidence of a more direct kind I have done two experiments, one with the O_2 line, the other with the H_2O line In the first the discharge tube was run with oxygen giving a strong line O_2 at 32 Now if O^{18} exists, there would be a line due to the molecule $O^{16}O^{18}$ at 34 of a strength directly proportional to the quantity of O^{18} present With half an hour exposure a barely visible effect at 34 was obtained Its relative intensity was measured by photometry against other and very short exposures of line 32 and came out at 0 14 per cent This very faint effect may, in my opinion, be due to traces of S^{34}

In the second experiment water vapour was

employed, and the faint line at 20 compared with the strong one at 18 in the same way. Here the effect was rather greater, amounting to 0.32 per cent. In an apparatus to which air has to be frequently admitted, one would expect some effect due to A^{40++} and Ne^{20}, but I think in this case it is to be ascribed mainly to $Si^{28}C^{++}$. In any event, the presence of the line may be explained without recourse to an unknown body.

If it can be shown that the absorption band effects are compatible quantitatively with the presence of the hypothetical isotope in proportion less than one part in 500, the matter will require further investigation. Otherwise it seems more reasonable to seek for them an alternative explanation and continue for the present to regard oxygen as a simple element.

Tsetse Fly and Big Game

REFERRING to an editorial entitled "A Threat to the Zululand Game Reserves" in NATURE of Nov. 24, 1928, whilst very much in sympathy with the object of this article in so far as it refers to preservation in reserves of the natural fauna of South Africa, I am led to express the opinion that certain of the statements made would be very difficult to substantiate on the basis of available scientific data.

The article gives the impression of having been written rather from a partisan point of view than from that of a detached scientific reviewer. The relation between certain species of tsetse fly and game is certainly a controversial subject, but it is considerably less so amongst those best acquainted with the tsetse fly problem than some ardent advocates of indiscriminate game preservation would have the world believe. In any case one does not expect NATURE to ignore the views of the leading entomological investigators on such a question. I may also point out that the *Journal of the Society for the Preservation of the Fauna of the Empire* is scarcely the publication in which one would expect to find unbiased views on this subject.

Justification for my venturing to offer criticism is to be found in the fact that a misstatement is included concerning certain experiments stated to have been carried out in this Colony, and further in the fact that vigorous efforts are being made by my Government at the present time to arrest the spread of tsetse fly in certain areas through reduction and control of game.

The misstatement referred to is contained in the passage, "On the other hand, satisfactory and unobjectionable methods of extirpating the tsetse fly and reducing the incidence of nagana in domestic stock are known, as has been shown by experiments carried out in Southern Rhodesia, where the bush itself, the winter retreat of the tsetse fly, has been attacked." It is true that many years ago, impressed by the apparent segregation of *Glossina morsitans* in shady forest during the latter part of the dry season, I suggested that in some localities destruction of these haunts might prove a practical method of eliminating the fly. It is also true that some experiments along these lines have been attempted in the Colony. It is not, however, true that these experiments have revealed a "satisfactory and unobjectionable" method of extirpating tsetse fly. In the first place, they have never been pursued to a satisfactory conclusion, and in the second, it is more than doubtful if they can be described as "unobjectionable" either from the sentimental or practical point of view. Surely to the Nature lover large scale destruction of many of the most conspicuous and beautiful representatives of the natural flora must be equally objectionable as destruction of the fauna. The game in any case is capable of more rapid recovery than the forest, providing, of course, that in neither case is reduction pursued to extermination. From the practical point of view there is, of course, no question concerning the objection to the destruction of useful timber.

Careful perusal of the article reveals the fact that the ultimate dependence on the game of such species of tsetse fly as *Glossina morsitans* and *G. pallidipes* is not actually called in question. I take it, therefore, that the main contention is that it is not possible or not practicable to reduce the game sufficiently to make conditions unsuited to the fly, and that attempts to do so may have untoward consequences.

With reference to the possibility of game extermination aggravating the trouble in respect to domestic animals, I may state that the experience in this Colony is that any developments of this nature following persecution of the game have been very limited and of a purely temporary nature. So far, the final event has been a marked improvement on the original position.

It is noted that no reference is made to the possibility of tsetse fly being scattered by other methods involving interference with conditions in a fly belt. Wholesale destruction of the forest in a fly belt in the Hartley district of this Colony in 1913 was certainly followed by the temporary appearance of trypanosomiasis farther afield than it had occurred for years, although the number of flies present was exceedingly small. Had this belt been heavily infested, it is at least possible that much more serious losses might have been sustained. The final event in this case was, however, also satisfactory.

With regard to the next sentence, justification appears to be lacking for the statement that "total extermination of all wild carriers of nagana which the policy demands if it is to be effective." On the contrary, experience in South Africa indicates that total extermination of game is by no means necessary to get rid of certain species of tsetse fly and the diseases they convey. The bibliography in Austen's "Monograph of the Tsetse Flies" contains notes of interest in this connexion. The late Mr. Claude Fuller has also collected a number of valuable records in the Transvaal. Dr. Schwetz has recently pointed out how tsetse fly has receded with the game around Elizabethville in the Katanga. There is a considerable amount of additional evidence in this Colony.

"It is believed that the segregation of game in reserves tends to keep the tsetse fly restricted to definite areas." Segregation of game presumably implies a game reserve surrounded by game free country. Certainly, maintenance of a game reserve will not restrict the range of tsetse fly, if conditions are suited to its perpetuation outside the reserve. The inhibiting factor would, therefore, be found in surrounding conditions not the reserve itself. The suggestion that it is possible to reduce the game sufficiently around a reserve to produce conditions unsuited to the fly appears scarcely in accord with what is apparently the main contention of the article.

The statement that "slaughter of big game ... has not succeeded, and cannot succeed, in reducing the numbers of tsetse" is an assertion which ignores the whole record of tsetse fly in South Africa and the published work of investigators fully qualified to formulate an opinion on this subject. A good case can certainly be made out for the view that slaughter of big game has in the past succeeded very markedly not only in reducing the numbers of tsetse (*G. morsitans*

and *G pallidipes*) but in eliminating these insects from considerable areas It is also not difficult to offer a plausible explanation of how this slaughter, falling short of extermination, would tend to eradicate these flies Whilst the case may not be considered absolutely proved, there is no justification whatsoever for unconditional denial of the possibility of controlling tsetse fly through the game, particularly in limited areas

I have no intention of entering into the controversy as to whether the Zululand game reserve should be abolished or otherwise My object is purely to deprecate the appearance in a leading article in NATURE of unqualified statements which are open to challenge, and the treatment of a scientific and economic problem from a less dispassionate point of view than readers of NATURE have learnt to expect

RUPERT W JACK
(Chief Entomologist)
Department of Agriculture,
Salisbury, Southern Rhodesia,
Feb 4

READERS of NATURE are familiar with the controversy which has raged round the question of coincident game and tsetse extermination, and the article referred to was obviously not a full summary of the divergent views, as was implied in the words "many competent observers hold," etc It was meant to point to considerations which seemed to have been overlooked in the case of the Zululand Reserves In view of the crude method of game extermination which has been widely advocated, it is regrettable that the experimental destruction of the segregation haunts of tsetse, which seems to have been based upon sound entomological observation, was not pursued to finality, as we had understood, especially as Mr Jack admits that the less scientific wholesale destruction of a forest fly belt had satisfactory results The fact that some years ago "an ill advised game drive [in the Zululand region to which the original article referred], by scattering animals over farms in the neighbourhood, undoubtedly led to the infection of the cattle of colonists by nagana and it is alleged that about 1000 head died," strongly suggests that segregation in the reserve area limited the incidence of the disease Finally, Mr Jack's own report of 1926 on the "Tsetse Fly in the Lomagundi District" largely quoted by the *Journal of the Society for the Preservation of the Fauna of the Empire* (1926), the impartiality of which he impugns, indicated, by its comparison between the anti nagana results of present day settlement and the pioneer settlements in South Africa, that the rapid retiral of big game in fact its local extermination, and nothing short of that, was the predominant cause of the disappearance of tsetse

THE WRITER OF THE ARTICLE

Knock Ratings of Pure Hydrocarbons

IN their letter on page 276 of NATURE of Feb 23, Prof Nash and Mr Howes point out the value of unsaturated hydrocarbons in suppressing knocking Their figures show that benzene and toluene, which for some time were considered the most effective anti knock hydrocarbons, actually possess this property to a very much smaller extent than many unsaturated hydrocarbons, particularly in the aliphatic series The statement that pseudocumene has pro knock tendencies is, however, misleading, particularly as Edgar's octane (1 1 3 trimethylpentane) is referred to in the same paragraph as a valuable anti knock Pseudocumene may be pro knock when compared with benzene, but it is certainly not pro knock in the general meaning of the term Compared with benzole in high concentrations, Edgar's octane is also pro knock The terms pro knock and anti knock are used rather loosely, and it must be remembered that they only have a definite meaning when a standard fuel is mentioned

Although our own results for the hydrocarbons tested by Prof Nash and Mr Howes fall in approximately the same order, there is one very noticeable exception We find that diamylene is not such a good anti knock hydrocarbon as they indicate, and that it certainly is not better than the parent hydrocarbon, trimethyl ethylene, from which it is derived If this were true, as Prof Nash and Mr Howes' figures indicate, it would then be desirable to polymerise the lower unsaturated hydrocarbons as Reiman does in the patent quoted, which would be contrary to all refining experience, in which it has always been found that the treatment of any unsaturated product involving polymerisation always reduces the anti knock properties Our own figures for diamylene prepared from trimethylethylene by polymerisation with sulphuric acid, and also for diamylene obtained by fractionating the high boiling hydrocarbons formed when commercial amyl alcohol is treated with zinc chloride are much lower than those obtained for trimethylethylene in equivalent concentration Furthermore, the fractions from the latter source boiling over the range containing the triamylenes after suitable purification, give even lower figures than those obtained for diamylene This result was only to be expected

AUDIBILITY TEST ON RICARDO E 5 ENGINE

	H U C R	Change in H U C R	n Heptane Benzene Equivalent (By Volume)	
			Per cent	
Standard reference fuel	6 3		44 7	55 3
Trimethylethylene	7 2	+0 9	29 7	70 3
Diamylene from trimethylethylene	6 96	+0 66	32 3	67 7
Diamylene from coml amyl alcohol	6 90	+0 60	33 2	66 8
Triamylene b p 240°–250° C	6 56	+0 26	39 0	61 0

The substances were tested in 20 per cent (by weight) concentration in standard fuel Every substance was tested over as wide a range of concentration as possible partly to reduce experimental error, and also because the relation between concentration and anti knock value is not necessarily linear When comparing polymerides, it is of course essential to work in weight concentration, as polymerisation does not involve a change in weight but generally one of volume

Results confirming the observation that polymerisation reduces the anti knock value were also obtained for methyl*cyclo*hexene and its dimeride methyl*cyclo*hexyl methyl*cyclo*hexene

AUDIBILITY TESTS ON RICARDO E 5 ENGINE

	H U C R	Change in H U C R	n Heptane Benzene Equivalent (By Volume)	
			Per cent	
Standard reference fuel	6 3		44 7	55 3
Methyl*cyclo*hexene	7 02	+0 72	31 7	68 3
Methyl*cyclo*hexyl methyl*cyclo*hexene	6 50	+0 20	40 1	59 9

The substances were tested in 20 per cent concentration (by weight) in standard fuel

While testing *cyclo*hexene a very interesting observation was made It was found that the value in any definite concentration was determined by the history of the sample For example, a sample which had been standing in the laboratory improved in anti knock value when distilled over sodium On exposure to light and air this value fell rapidly, another sample, stored in a brown bottle, did not deteriorate nearly so rapidly Eventually this behaviour was traced to the presence of traces of *cyclo*hexene peroxide, which is readily formed under the conditions described (compare *J A C S*, 50, 568, 1928) This peroxide appears to be quite stable in solution and to accumulate on storage The following are the figures obtained

AUDIBILITY AND BOUNCING PIN TESTS ON ARMSTRONG ENGINE

		H U C R	Change in H U C R	n Heptane Benzene Equivalent (By Volume)	
				Per cent	
Standard reference fuel		5 6		44 7	55 3
*Cyclo*hexene					
Refluxed 48 hours over sodium Maximum value	20% solution by weight.	6 25	+0 65	34 9	65 1
Exposed to light and air six months	20% solution by weight.	5 46	−0 14	47 3	52 7
Stored in brown bottle in diffused light six months	20% solution by weight.	6 07	+0 47	36 8	63 2

Not all unsaturated hydrocarbons, however, appear to form peroxides so readily, often, if they do, decomposition occurs with the deposition of gum The sample of *cyclo*hexene left in the light for six months deposited no visible gum

The importance of testing unsaturated hydrocarbons to make sure that no peroxides are present must be emphasised, as the values obtained may be erroneous if this precaution is not adopted Rough analyses of the samples of *cyclo*hexene referred to above gave 0 2 gm peroxide oxygen per litre for the sample left in the light, and 0 009 gm per litre for the other sample It is interesting to note that *cyclo*hexene in contact with air shows indications of the presence of peroxides after a short exposure to ultra violet light

The observations of Prof Nash and Mr Howes that the olefines, which are comparatively stable towards certain oxidising agents, are the most effective in suppressing knocking, agrees well with our own In general, we have found that comparing isomerides, the more compact a hydrocarbon molecule is the greater is its tendency to suppress knocking Thus trimethylethylene is better than pentene—2 This conclusion is in agreement with Dr Edgar's observation with regard to the isomeric heptanes

The effect of introducing a second double bond is interesting Of the hydrocarbons examined, those containing conjugated double bonds (*e g* $\beta\gamma$ dimethylbutadiene, $\Delta^{1\,3}$ *cyclo*hexadiene and butadiene) have excellent anti knock properties. A diolefine in which the double bonds are not conjugated (*e g* diallyl) does not possess particularly marked anti knock properties In this connexion the effect of introducing double bonds into a *cyclo*hexane ring is interesting

The substances were tested in 20 per cent concentration by weight

The difficulty of correlating engine tests with conventional formulæ at once becomes apparent

Another point of interest is the effect of the side chain attached to a benzene ring Although it is now well known that an increase in the length of the chain

AUDIBILITY TEST ON RICARDO E 5 ENGINE

	H U C R	Change in H U C R	n Heptane Benzene Equivalent (By Volume)	
			Per cent	
Standard reference fuel	6 3			
*Cyclo*hexane	6 56	+0 26	39 0	61 0
*Cyclo*hexene	6 76	+0 46	35 4	64 6
$\Delta^{1\,3}$ *cyclo*hexadiene	7 32	+1 02	28 7	71 3
Benzene	6 57	+0 27	38 8	61 2

reduces the anti knocking properties, the opposite effect is found with side chains attached to benzene rings For example, toluene has greater knock suppressing tendencies than benzene, ethylbenzene than toluene, and propylbenzene than ethylbenzene Yet xylene is inferior to ethylbenzene as an anti knock, and pseudocumene is stated to be similarly inferior to benzene Any theory which can explain all these facts must of necessity be very elastic

Swirl Opalescence

WHEN preparing the lecithin cholesterol suspension required for the reaction of Murata (*Jap Zeit für Derm u Urol*, 22, No 11, 1922, *Sci Reports Japanese Gov Inst Infect Dis*, vol 2, 1923), I noticed that the most effective suspension was one which was free from visible suspended particles when freshly prepared, though the converse—that any truly colloidal suspension was suitable—was not true The author did not note the point among his elaborate directions He directed that the suspension should be used after standing about twenty minutes Since at the end of this time the suspension begins to show a faint nacreous opalescence which is not removed by filtration through ordinary filter paper, it is possible that the reaction depends in some way upon a change of state from the truly colloidal to the condition of a coarse suspension It may be remarked that for the Wassermann antigen containing the same components an approximately colloidal state is not requisite

It is interesting to inquire upon what the property of swirl opalescence depends The phenomenon is well shown by so called gold paints and similar preparations, which are suspensions of small metallic flakes formed by stamping a suitable metal Since these preparations show a high degree of swirl effect, it might be thought that a laminar structure of the suspended solid would be a necessary condition for the manifestation of the phenomenon It is nevertheless difficult to demonstrate the effect well with aqueous suspensions of cholesterol, although the typical crystal of cholesterol is a lamina Blood corpuscles in urine or isotonic saline show swirl opalescence, but to a smaller degree than does a suspension of coliform organisms Suspensions of cocci do not show the phenomenon

Since swirling produces a local orientation of liquid into parallel planes, swirl opalescence may be taken to result from locally regular reflection of light from particles in these planes The particles must be

opaque, and good reflectors, or possess a refractive index differing sufficiently from the refractive index of the medium Moreover, they must have at least one dimension considerable with respect to the other one or two dimensions, in order to provide the turning moment which shall set them finally along the plane of the stream Thus the phenomenon may be shown not only by lamellar structures, but also by bacilli and acicular crystals

Probably the best known example of the phenomenon is afforded by a familiar brand of household ammonia, in which minute crystals of salts of the higher fatty acids are suspended Microscopic examination shows that the crystals are acicular, or plumose Suspensions of benzidine in very dilute alcohol show a high degree of opalescence Commercial solid recrystallised benzidine appears laminar to the naked eye, and if it is dissolved in alcohol and allowed to evaporate, a mass of broad thin plates, often of considerable length, is seen Support is thereby suggested for the presence of laminæ in its opalescent suspension, but further examination did not altogether confirm that theory

A suspension was prepared by rapidly adding 0 5 c c of a hot 2 per cent alcoholic solution of benzidine to about 50 c c of water at room temperature Microscopic examination on a slide without a cover glass, of a drop of the suspension, showed a number of acicular crystals, with a larger proportion of almost circular, very thin, platelets A film formed on the surface, and the film was almost entirely composed of aggregated platelets When the drop was examined in a covered hæmocytometer chamber, acicular crystals preponderated the platelets appeared to be the product of slow evaporation, and were the chief forms in a film which formed on the surface of the bulk of the suspension Two other suspensions were prepared similarly, except that for one the water was warmed to about 30°, and the other was warmed to that temperature after addition of the benzidine solution When these clear solutions had cooled they deposited crystals just visible to the naked eye, and the opalescence differed much in degree and kind from that of the unheated suspensions Microscopic examination showed that the crystals were almost entirely lamellar agglutinations, which, probably owing to their extreme thinness, had far less effect in producing opalescence than had the acicular forms

To the question why a definitely acicular crystal, such as lead iodide, does not give more than an incipient swirl opalescence, the reply may be suggested that it is partly because its high specific gravity favours rapid settling, and partly because the crystals are relatively large, that is, their number in a given volume is not great enough to enable them to reflect light with sufficient regularity The relatively large lamellar particles of gold paints each reflect an appreciable amount of light, making up in surface what they lack in numbers

Rigidity in Weak Clay Suspensions

IN the course of work necessitating the purification of quantities of the smallest soil particles (the so called clay fraction), a striking phenomenon was observed during the flocculation and sedimentation of the material in dilute hydrochloric acid Many industrial and laboratory processes entail flocculation and sedimentation, so an account of our own observations may be of general interest When the concentration of the suspension exceeds a certain critical value—the significance of which will appear later—a number of sharp ramifying fissures develop containing clear liquid The density of this being less than that of the surrounding clay laden liquid, a circulation is set up, clear liquid rising through the fissures while the remainder sinks Some of the fissures form against the glass walls of the vessel, so the progress of sedimentation can be watched in detail Near the bottom of the vessel the fissures tend to close, and to enlarge progressively towards the top of the column into conical chimneys, through which the motion of the ascending liquid can be traced by the movement of floccules detached from the walls of the fissures The circulation is completed by the deposition of these floccules in a crater or ring around the exit of the chimney There is no doubt that the suspension has acquired rigidity The descending surface retains the initial form impressed on it by the curvature of the meniscus and by occasional air bubbles floating on the water Marks deliberately made on the clay surface with a rod are also retained

Weaker concentrations settle much more rapidly,

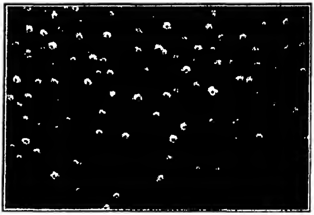

FIG 1

in those less than one quarter of the critical, the floccules fall individually, whereas at half the critical value the floccules settle *en masse*, leaving a clear supernatant liquid In the latter case the suspension subsides with a perfectly flat surface, which, when disturbed, shows no sign of rigidity But as the flocks settle on the bottom of the vessel, a layer is built up which has a concentration great enough to show rigidity The chimneys already described then form, and extend progressively upwards towards the descending surface When this is still about 1 cm above the tops of the chimneys, discrete domes, often exceeding 1 mm in height and 1 cm across, are formed over them, and finally each mound develops a well defined hole at the summit This stage is shown in the accompanying photograph (Fig 1)

It would appear that the clay concentration in the upper layers at the moment of perforation of the mounds is the minimum at which rigidity can occur An independent test of this point was suggested by other work in progress in this department on the plastic properties of soil and clay pastes measurements of the rate of flow through a capillary tube under different stresses have demonstrated that departure from the Poiseuille Law occurs only above a certain critical concentration For our suspensions this value was found to be identical, within the limits

of experimental error, with that in the immediate neighbourhood of the perforated mounds as determined directly on a sample removed with a pipette The agreement is not affected either by removing the coarser clay particles or by the addition of fine silt, but, as would be expected, the critical concentration increases with the coarseness of the suspension It is interesting to note that the critical concentration, even in the coarser suspensions, is only about 1 5 per cent by volume

The above remarks apply to the case in which the minimum amount of electrolyte for flocculation was used ($N/1000$, HCl) Parallel experiments with strengths up to $N/100$ show that the amount of electrolyte present is not without influence on the phenomenon For example, the minimum concentration for rigidity, as determined in the plastometer, is now above that at which mounds develop in sedimentation experiments There is evidence that this is due to thixotropic gel formation, that is broken down in the preliminary shearing given to the clay in the plastometer before measurements are begun This possibility will be followed up during further investigations of the phenomenon now in progress

Modes of Distribution of the Mudfish in the Philippines

ON Luzon, the main island of the Philippine archipelago, there are only two real seasonal variations, known as the dry and the wet or rainy seasons During the dry season, October to May, there is practically no rain At this time the smaller bodies of water dry out, and lower fields are covered with cracks crevices and clods running in all directions Water remains then only in isolated deeper ditches, swamps, and larger rivers During the rainy season, June to September, everything is flooded Not only the swamps and ditches, but even the rice fields are full of water This is especially true in the eastern part of the island At this time thousands of small fish appear in the rice paddies They are the young of the fish *Ophiocephalus striatus* Bloch, which is known in English as *mudfish* and in Tagalog as *dalag* The young fry is known to Tagalogs either as *bulig* or as *anak nang dalag*, that is, the children of dalag

The Tagalogs have a number of theories concerning the occurrence of this fry in the rice fields Some hold that it originates from the mud, others that it rains down from clouds, still others, claiming some education, think that the old fish aestivates in the mud, and then when the rains come they emerge and lay the eggs Some even think that the eggs are laid in the preceding year, remain dormant during the dry season, and hatch when the rains come The first two notions need not be considered seriously here The third theory, that the fish can survive in dry mud some five or six months, has no proof The dalag, aided by its accessory respiratory apparatus, may live in water which is not fit for any other fish to live, but when it comes to a complete absence of water, the situation is changed It may live for two or three days on a wet market table, but when it jumps out from an aquarium on the laboratory floor in evening, it never survives until the morning During my five years' residence in that part of the Islands I have never been able to learn from the people of a case where a fish could survive in the mud during the dry season, and I have been making constant inquiries, especially from the country people The eggs are also very sensitive to the external surroundings Normally they hatch within two or three days, and do not live through any greater length of time without hatching

There are three possibilities which may account for the occurrence of the young fish in the rice paddies The old dalags may swim from rivers into flooded fields and then lay their eggs There are many well-known instances where freshwater fishes leave the deeper waters for spawning purpose The dalag is not very particular in this respect but some of them do actually migrate from deeper to shallower waters, though they seldom reach the rice fields The young fish if hatched near the rice fields may easily swim into them They are strongly positively rheotropic, and very good swimmers The waters receding from the rice fields give the young fish an opportunity to reach them These two modes of distribution account for a considerable number of cases but the most important mode of distribution is by means of the eggs themselves

The eggs of dalag are 'pelagic' or floating eggs They are quite large (1 25 1 5 mm), have the germinal discs on one pole, and an oil droplet on the other The oil being lighter than water buoys the eggs, so that it floats on the surface in such a way that the germinal disc is always submerged just under the surface of the water where the conditions for its development may be considered the best Such eggs float very easily in any direction, depending upon the wind During the rainy season the typhoons bring very strong winds When the fields are flooded and the boundaries between the larger bodies of water and the rice paddies disappear, the wind carries the eggs there In such a way the eggs may be carried into most unlikely places After a strong typhoon in Manila, 1927, large numbers of eggs were brought to the University of the Philippines Rizal Hall, right to the door of the Zoology Laboratory At a distance of about 300 metres on the opposite side of the campus is located a drainage tube leading indirectly to Pasig River The drainage path itself is more than 300 metres long The campus is dry throughout the year with the exception of a short time during the stronger typhoons when it may be submerged for a few days Much better means of communication are found at such times between the rice fields and the larger bodies of water and I think that this is the most important means for the distribution of dalag in the rice fields

Major Segrave's Speed Record of 231 m p h

THERE has been much self satisfied amusement over the five places of decimals in which Major Segrave's speed record on Mar 21 was recorded in the Press Truly these are merely arithmetical residues—a waste product A lad with a healthy sense of what is the good part of an apple scoffs at saving up the skin for microscopic study—it is a waste product

Let us take to the microscope—at the cost of knowing a little more and laughing a little less

To the Royal Automobile Club, Sir Charles Wakefield gave not only a £1000 Trophy but also a £1000 a year for the 'world's record' holder until he is beaten If the amount were 6d the moral compulsion to enforce the letter of the law in sporting matters remains, but I quote the amounts to impress the Philistines

Now thirty years' evolution of motor racing has

saddled us with history, precedents and rules In this case the rules call for

(1) A level track of officially certified length properly surveyed—gradient tolerance, etc
(2) Automatic timing to $\frac{1}{100}$ sec
(3) A to and fro run—not only to eliminate gradient effect but also to average the wind effect (otherwise *all* attempts would be made in a following gale of wind)

Following horse racing precedent, the *written record* itself was not a velocity in miles per hour, but a *time* It was the average of the two times actually measured For popular consumption a speed has been worked out from this mean time and this, though it is *not* the speed of the vehicle, is universally taken as such, and it is now treated as the record

(I explain that the true mean speed is the mean of the two speeds, on the runs, and not the result of dividing the length by the mean of the two times) When a record has stood unquestioned beyond the delay for appeal it is established and cannot be altered This protects holders from having to fight for their title up to an indefinite date Looking as we are through a microscope, all this is very wrong scientifically—in practice it is not very significant

Now in doing the prescribed arithmetic there appear these wasted decimals and no provision for ignoring them The first step to a remedy is to pass a new rule that records shall not be deemed beaten unless the new performance exceeds the last by x m p h , and such a resolution has been placed on the agenda of the A I A (The International Association of Automobile Clubs) by the Royal Automobile Club, but I greatly doubt if it will be carried—for two reasons

(1) Rigidly speaking, a bit of true speed should not be added to a numeral which is not a speed
(2) In fairness to the next competitor, the existing record holder should not be protected in his tenure of the spoils (the £1000 a year) with an excess—which he himself was not subjected to, since this partakes of altering the rules of a contest while it is in being

Those who say that I am caring *de minimis*, do not realise how jealously these preferences, however small, are regarded Reason (2) will not, I surmise, be raised, but it may well dominate the discussion What will be raised is the objection to breaking the comparative position of the items in the list of records The War has probably played havoc with the archives of the earlier records so that they could not well be written up in terms of the new method of calculation (mean of velocities in lieu of mean of times)

For the ordinary man the speeds are substantially as given for the clever man they are still as given, and in addition they afford him the added pleasure of feeling clever Shall we not continue to spread happiness among the wise ? MERVYN O GORMAN

Colour and Optical Anisotropy of Organic Compounds

I DESIRE to direct attention to a significant and very generally valid relation which emerges from an examination of the data accumulated by eight years of systematic research at Calcutta on the scattering of light The generalisation may be stated thus *The types of molecular structure in carbon compounds which favour the development of colour are those which exhibit an exceptionally high degree of optical anisotropy*

When we compare a series of compounds in respect of their optical anisotropy, and their colour as indicated by the position of their absorption bands in the spectrum, the parallelism between the development of the two characters becomes evident Thus, the aromatic series of compounds are generally more anisotropic than the aliphatic series We have large increases of anisotropy when we pass from pyridine to quinoline, or from benzene to naphthalene and thence to anthracene The introduction of a chromophore like NO_2 or auxochrome like NH_2 as a substituent in the benzene molecule produces a notable increase in anisotropy Less striking but perfectly definite increases occur when halogens of increasing atomic weight replace the hydrogen atom in the benzene ring In the disubstituted benzene derivatives, the relative position of the groups influences the anisotropy appreciably These and many other instances may be cited to show that an increase in optical anisotropy connotes a development of colour

That variations of structure in carbon compounds should influence the two optical characters of anisotropy and colour in similar ways need not occasion surprise when we recollect that the element carbon in its two states, diamond and graphite, itself exhibits the same tendency Diamond is a transparent and isotropic dielectric, while graphite is opaque conducts electricity, and has a highly anisotropic structure as shown by X ray analysis and by its diamagnetic behaviour C V RAMAN

Magnetic Storm of Feb 26 28, 1929

IN the Astronomical Column of NATURE of Mar 9, mention is made of the auroral display of Feb 27 The display, as seen from various places in the British Isles, particularly in north east Scotland has been fairly fully described in the daily press The accompanying magnetic storm was notable on account of the magnitude of the fluctuations of magnetic force A detailed description of the storm would occupy too much space, but information on any particular point could of course be given, on application, to anyone interested

At the Lerwick and Eskdalemuir magnetic observatories, it has been customary for some time to run additional auxiliary sets of magnetographs of lower sensitivity than the standard instruments, so that a reasonably complete record, even of the extreme fluctuations in storms, may be available In the present case Mr Lee of Lerwick Observatory reports that the lower limit of registration, even of the auxiliary Horizontal Force instrument, was exceeded from 28 d 1 h 3 m to 8 m The ranges of variation actually recorded at Lerwick were 3° 57 in Declination, $>1885\gamma$ in Horizontal Force and 940γ in Vertical Force ($1\gamma = 10^{-5}$ C G S units) At Eskdalemuir, as is usually the case in the great storms, the ranges were of roughly half the above order, being in fact 2° 8 8 in Declination, 916γ in Horizontal Force, and about 690γ in Vertical Force

The last occurrence of a storm with variations of magnetic force of the above order was on Oct 13–16, 1926 On that occasion a magnificent auroral corona was seen from many parts of the British Isles and northern Europe The ranges recorded at that time were, at Lerwick, 3° 41 in Declination, $>1068\gamma$ in Horizontal Force and $>2086\gamma$ in Vertical Force , and at Eskdalemuir $>957\gamma$ in the West Component, $>719\gamma$ in the North Component, and $>624\gamma$ in the Vertical Component A H R GOLDIE

The Bronze Age in Southern Africa

By Prof RAYMOND A DART, University of the Witwatersrand

IN view of the impetus which has been given to the metallurgical analysis of ancient copper and bronze objects by the initial investigations of Prof John Sebelien of Aas, Norway (NATURE, Jan 10, 1924), and the practical activity of the British Association Research Committee which has resulted in the important interim report embodying the recent investigations of Prof C H Desch (NATURE, Dec 8, 1928), it is ardently to be hoped that funds will not be lacking for following up Prof Bernard W Holman s suggestions (NATURE, Dec 29, 1928) concerning the further collection and publication of data about the ancient mining industry and the products thereof which are available in southern Africa

It has been the uniform experience of those who have investigated the ancient mining industry in South Africa that the work has been on so gigantic a scale as to preclude any belief that the products of the industry were consumed by a local population Beginning with the investigations of Mr T G Trevor, at that time Inspector of Mines for the Union Government, and now holding a similar post for the Rhodesian Government, several important papers by Woodburn and Baumann and others have been published in the *Journal* of the Chemical, Metallurgical, and Mining Society of South Africa which established not only the above mentioned conclusion but also the further important deduction that the early copper tin, micaceous iron and ochre getters had the same sort of industrial implements as the ancient gold getters of Rhodesia and the north eastern Transvaal

On similar lines of reasoning it was possible for me (NATURE, June 21, 1924), by gathering together information from these and other sources, as well as by my personal investigations, to put forward the thesis that the enormous ancient mining district from Katanga and Broken Hill to Pretoria, and from the Kalahari to the eastern coast, formed a single cultural unit

In the *South African Geographical Journal* of that year I developed the same view in an article on "The Ancient Mining Industry in South Africa," and in NATURE, Mar 21, 1925, p 425, was enabled, through the remarkable researches of Bro Otto, to demonstrate some of the objective proofs that are to be discovered in Bushman cave shelter paintings in the Cape Province, Natal, and Rhodesia of alien intruders wearing headgear of Babylonian and Phrygian appearance

The great age of at least one of the mines was demonstrated by me in "The Rooiberg Cranium" (*S A Journal of Science*, vol 21, 1924), when I pointed out the existence of a stalagmite fifteen feet high and eight feet thick, in its narrowest part, extending from the roof to the floor, thirty to forty feet from the entrance and in such a position as to render practically certain its formation since the period of occupation by the miners

It was, therefore, with considerable confidence that I boldly suggested in my article on "Nickel in Ancient Bronzes" (1924) that, as Sebelien had failed to find nickel carrying ores in the sites of ancient mines in the Arabian and Mediterranean areas, the probable source of the nickel contaminated copper and tin for the ancient Near East was southern Africa

At that time, although it was known that there was ample evidence of smelting operations in the Rooiberg area and a piece of bronze slag had been discovered which had provided in the hands of Mr Schoch the analysis revealing about 3 0 per cent of nickel which has now proved of such significance, there was no conclusive proof that bronze had been intentionally fabricated at Rooiberg

This important corroboration of the view advanced by me was forthcoming at the Pretoria meeting of the South African Association (1926), when Dr Percy A Wagner (*S A Journal of Science*, 1926) revealed the amazing discovery of Mr Gordon of no fewer than thirty distinct furnaces on the farm Blaauwbank No 433 and alongside of some of them small separate stacks of hand cobbed tin and copper ore also accumulations of nodular aluminous surface limestone and hand cobbed iron evidently used as a flux In the furnaces themselves were found slugs' and frills' of bronze, many of them still embedded in an iron rich slag The largest slug weighs 31 3 grammes"

Here, then, as Dr Wagner stated is definite proof for the first time that these ancient metallurgists had deliberately set out to make bronze, and that they were thus evidently acquainted with the properties and uses of that important alloy

The reason for the admixture of nickel with the ores at Blaauwbank by the bronze makers was also proposed by Dr Wagner, who pointed out that on the farm there is, in addition to important tin and copper deposits, a nickel lode carrying at the outcrop big masses of apple green nickel bloom' or anabergite This bears a remote resemblance to malachite, and it is probable that the ancient miners, who could not fail to have noticed this outcrop, mistook it for that mineral and thus introduced nickel into their bronze' The objects demonstrated by Dr Wagner are now in the Social Anthropology Museum of the University of the Witwatersrand

Irrespective of any other question there has, therefore, been established by incontrovertible evidence the existence in South Africa of a definite Bronze Age period Such a phase of South African prehistory has not hitherto been recognised by antiquarians, and naturally enough since the bronze objects which in other lands symbolise the existence of such a period have not been found here, but rather only the raw materials of mines, furnaces, and dumps which must have contributed to the blatant bronze cultures of more advanced cultural centres

The second conclusion that is warranted from the facts is that the 'ancient mining period" in South Africa dates back to the Bronze Age, seeing that the

methods of exploitation of the copper, tin, gold, and iron fields are culturally uniform It can scarcely be that the whole industry was of one age its very immensity demonstrates that it must have had several phases The remote antiquity of at least one phase cannot, however, be questioned

It is of the utmost importance that the Bantu peoples when first discovered did not belong to a 'bronze' but to an 'iron' culture, and there is no evidence to show that they evolved through a bronze phase to the iron phase We are forced to conclude that the highly intricate metallurgical processes of bronze making demonstrated by the deposits at Blaauwbank betray the actual presence there at a remote age of skilled and intelligent craftsmen from a superior cultural area Seeing that the deposits are half way across the continent, some estimate may also be arrived at concerning the lengthy period of South Africa's exploitation by that superior race utilising the bronze

To the physical anthropologist who has lived in South Africa and had the opportunity of seeing and dissecting representatives of practically every tribe in the south eastern end of the continent, there is concrete evidence in the thousands of negroid inhabitants with straight, aquiline, and hooked noses, elevated nasal bridges, reduced lip fullness, and lack of prognathism, to demonstrate beyond cavil the flood of Semitic and other Caucasian blood which flows in the veins of the Bantu peoples, just as the presence, in a more reduced proportion, of Mongoloid eye folds, slit like eyes, and high cheek bones of the "Snese Hottentoten" of the Eastern Province and the Bantu tribes of the eastern coast generally reveals past, but probably more recent and less widespread, contacts with the Far East

With regard to the actual date of the Bronze Age in South Africa, it seems clear that being provoked by one or more alien races who were interested in raw bronze and being absolutely dependent upon that alien interest (as the lack of a typical and separate local bronze industry, such as those of Europe, demonstrates), there can be little question that the South African Bronze Age synchronises with the Bronze Ages of the nearest ancient cultures, namely, those of Egypt and Sumeria The importance to South African prehistoric chronology of the further prosecution of this absorbing piece of detective work in metallurgy and the exact chronological establishment of the different ancient mining phases can scarcely be overrated

Fifty Years of Marine Refrigeration

THE important subject of refrigeration on shipboard has recently been dealt with in three papers by Mr A Greenfield, Mr G W Daniels, and Mr H J Ward, read respectively to the Institution of Marine Engineers, the British Association of Refrigeration, and the Institution of Mechanical Engineers

One of the earliest contributions to a technical society on this subject was the lecture of Alexander Kirk to the Institution of Civil Engineers in 1884, while two years later J B Lightfoot read a paper to the Institution of Mechanical Engineers on refrigerating and ice making machinery Associated with the production of artificial cold were the experiments and inventions of Cullen, Leslie, Carré, Gorrie, Tellier, the Bells, Coleman, Linde, Haslam, and others To Gorrie, an American doctor, we owe the first machine which caused compressed and cooled air to expand in working a piston in a cylinder, his patent being taken out on Aug 22, 1850 Five years later, Gorrie died at Apalachicola, Florida, and there are memorials to him in that city and in the Statuary Hall of the Capitol, Washington, D C It was not, however, until about twenty years later that the matter was taken up seriously, and refrigeration on shipboard may be said to have come in definitely with the voyage of s s *Strathleven* in 1879, just fifty years ago The *Strathleven* was fitted with a Bell Coleman cold air machine, and brought home a small cargo of frozen meat from Australia As Mr Ward said, that marked the economic beginning of the industry The Bell Coleman patents were then acquired by the late Sir Alfred Haslam, one of his first machines was fitted in the liner *Orient* in 1881, and in 1889 some 2,000,000 carcases of beef and mutton were brought to England, most of them in ships having Haslam's machines Compressed air machines then began to be replaced by machines using other gases, and to day about 80 per cent of refrigerated cargo ships use carbon dioxide and 18 per cent ammonia, the advantages and disadvantages of which were touched upon by both Mr Ward and Mr Greenfield

Nearly every writer on refrigeration acknowledges the great debt this branch of engineering owes to the scientific investigator, and frequent reference is made to the well known standard treatise, The Mechanical Production of Cold," by Sir Alfred Ewing Refrigeration in all its aspects is almost entirely the outcome of research, and the various investigations now being made by the Food Investigation Board, at the Low Temperature Research Station at Cambridge, and at the National Physical Laboratory, are of great value to the industry

Fish, meat, cheese, butter, apples, oranges, bananas all require different treatment, and the refrigerating engineer is faced with many problems Mr Greenfield's review of the arrangement of a large refrigerated cargo ship is of especial interest With a sectional profile of such a ship, he gave particulars of the mechanical appliances and piping The ship he described has 54 independent insulated cargo spaces of a total capacity of 560,900 cubic feet cooled by 37 miles of brine cooling pipe divided into numerous circuits The temperatures used vary from 10° to 20° F for fish and butter, to 34° to 40° F used for vegetables and fruit Frozen meat is kept between 16° to 24° F, and chilled meat at 29° or 30° F

Fruit was first brought to Great Britain from the

West Indies in 1886 in the s s *Nonpareil*, apples were successfully carried home from Australia in 1888 in the s s *Oceana*, while the banana trade began in 1900 "through the enterprise of a Liverpool shipowner who sought to aid a British colony at the call of a great Colonial Secretary" This trade has grown to such an extent that in 1927 more than 18,000,000 bunches of bananas were shipped from the Gulf ports to depots in Great Britain and European countries

Hitherto, refrigerating machinery has been driven by steam, but compressors and pumps are now sometimes connected to electric motors or to oil engines In one of the fine new Nelson liners, the motor ship *Highland Monarch*, of 14,137 tons gross, which made her maiden voyage last autumn, the insulated spaces have a capacity of 500,000 cubic feet The ammonia compression system of refrigeration with brine circulation is used, the ammonia compressors being driven directly by two four cylinder Diesel engines of 300 horse-power each Brine at four different temperatures is available for circulating through the various chambers, flow meters being used to indicate the amount flowing in each circuit All such installations are erected according to the rules and under the direction of the surveyors of Lloyd's Register, who also periodically inspect the ships on behalf of the insurance and other interests involved During 1927–28 installations were fitted in 62 vessels with a total insulated capacity of 5,500,000 cubic feet, while on June 30, 1928, 424 vessels held the Society's Refrigerating Machinery Certificate with a total capacity of more than 76,000,000 cubic feet of insulated space Ships, however, are but the connecting links between the producers abroad and the distributors at home, and the extensive nature of the refrigeration industry in Great Britain and Ireland can be judged from a glance at the Ice and Cold Storage Trades Directory for 1926, a book of some 236 pages

Evolution through Adaptation[1]

By Dr F A BATHER, F R S

It is a hundred years since Francis Egerton, Earl of Bridgewater, died, leaving a sum of money for the preparation and publication of works "On the Power, Wisdom, and Goodness of God as manifested in the Creation" At least half of the eight Bridgewater Treatises thus engendered exemplified their subject by the fitness mutually subsisting between living creatures and the outer world The facts which by them were so easily explained have presented to us one of the fundamental problems of biology The first question is How far are animals and plants really fitted to their surroundings? Then, if not, why not? And again, in so far as they are fitted, how did they become so?

No living being can be considered without its surroundings, indeed, it is hard in some respects to say where the creature ends and its surroundings begin An individual must be fitted to its surroundings, or must make some effort, conscious or unconscious, to become fitted Thus when we observe the multifarious forms of life fitted adequately, if not always perfectly, to varied habitats and modes of living, we need feel no surprise, and we perceive no difficult problem

Geology, however, has taught us that conditions have constantly been changing, and that the forms of life also have changed, and it has revealed to us a succession of creatures constantly becoming fitted, or as we say adapted, to diverse conditions The problem is no longer the fitness of the individual, but the adaptation of the race or lineage An individual is adaptable, but only up to a point, and any increased fitness of the individual is not—at any rate in the vast majority of cases open to human observation—handed on to the offspring How then are we to explain the fact that numberless series of forms have gradually changed, and so changed as either to accommodate themselves to changing conditions or to become (in most instances) more and more fitted to diverse states of life?

Many answers to this question have been propounded, but, since controversy still continues, it is plain that none of them is wholly satisfactory

A theory of revolutions of the earth's surface, each accompanied by a special creation of fresh forms of life, has long ceased to fit the known facts Even if an external guiding power were admitted, one would still seek to discover the mechanism through which it worked From such a theory it is but a step to the conception of development in definite directions, each according to some predetermined plan Palæontologists have indeed made known to us in various groups of animals numerous series, each apparently following a trend of evolution, and some have claimed each trend as inevitable and accident apart, predestined But it will be realised that any line of evolution, as we look backwards, appears to have been regular and inevitable From eolith to steel axe the ascent is straight and unbroken It is just because the later shape proceeds so naturally and, to all appearance, inevitably out of the former shape that we can speak of an unrolling or evolution But when we examine any such line more minutely we find that matters are not so simple Take the evolution of either the horse or the bicycle and it will be found that there are some side lines which failed to win approval, others that were adapted for special conditions and so diverged, or two stocks of different origin and structure may have been similarly moulded to meet a similar environment and have thus assumed a close resemblance Clearly predetermination cannot apply to such cases, and therefore cannot be called in as a general expression of evolution

Broadly speaking, there is a conflict between the view of evolution as essentially a process of

[1] From the Friday evening discourse, entitled "Lily-stars of the Sea How they Fit their Surroundings," delivered at the Royal Institution on Feb 22

adaptation, and the view that it follows predestined courses The essence of the latter view is that the trends do not necessarily accord with the surroundings, but may indeed run counter to them, so that the lineage ceases to be fitted and comes to an inevitable end Now it cannot be denied that, according to our present lights, there are such examples of evolution at cross purposes with environment Any solution of the problem of adaptation must apply also to maladaptation [8]

The problem may be limited and perhaps clarified if taken in connexion with another generalisation of palæontology—the irreversibility of evolution This, which we owe to Louis Dollo, states that a structure once lost is never regained Should the need again arise for the performance of the same function, some other organ must be modified for the purpose This irreversibility may be extended to the history of the lineage There is, all must admit, a curious parallelism between the development of the individual and that of the race , and, just as the individual's growth never really returns on itself, so is any true rejuvenation excluded from the history of the race More obviously connected with irreversibility is a further generalisation, particularly associated with the name of D Rosa, stating that a race as it progresses loses its power of adaptive change At first it can vary in numerous directions and is not bound to any one road But every step that it takes in one of those directions forbids its return to seek another path Thus by degrees all roads but one are barred to it, and if that one road ceases to lead to salvation, the race must perish

Let us combine these statements of palæontology with the geological teaching that from the beginning the surface of our planet has constantly been changing, a fact that has involved, *inter alia*, changes of climate, changes of depth and salinity in the waters, and migrations of their inhabitants It follows that the surroundings of a race are continuously altering , the race has perpetually to catch up with the change in so far as the external changes proceed in the same direction, so do adaptation and specialisation follow in what seems to be a definite trend Now suppose the external change to be diverted from the normal course, then a race that by its specialisation has cut off all chances of adaptation to the new conditions will necessarily perish Or suppose the external change merely to cease , it does not follow that the internal conditions of the organism will cease to move along the line hitherto found beneficial , thus arises the phenomenon of a trend which, beginning in harmony, has been turned to disharmony

This seems to be a fair expression of well known facts It suggests to us that not only is there irreversibility and a consequent loss of adaptability, but also that there is some tendency for change of form and structure to proceed in a definite direction In most cases the direction will accord with the environment , otherwise the world would cease to be peopled In the remainder, and eventually in all cases, the direction becomes in disaccord , the race dies out, and its place is taken by one more adaptable Hence special evolution of the race is replaced by that general evolution of the world-population which we call progress

Consideration of the two chief theories of the evolutionary process in the light of modern knowledge has seemed to point to this same conception of an internal direction

The Lamarckian theory, thus regarded, implies that a modification of the individual to meet the pressure of the environment is somehow transmitted to the germ cells, and that these produce an altered offspring, or mutant, already in accord with the environment It is generally agreed that characters are transmitted from parent to offspring through the chromosomes or nuclear elements of the germ-cells Now it is known that change of outer conditions (food, light, temperature, moisture, and the like) may have such a physico-chemical action on these chromosomes as to induce some change or mutation , but if, as the Lamarckian theory demands, the mutant produced is just the one that fulfils the requirements, we still have to ask why this should be so

In most cases that appear to exhibit a direct action of some outer physical agent, it may be that the agent merely stimulates mutation, and that among numerous mutants only those survive which harmonise with the environment The remainder may never actually come to birth, and even fertilisation may be hindered by a change in the germ-cell due to external influences Such instances in fact are familiar to geneticists When the stimulus of a changed condition is continued through long ages, the probability of its producing a mutant in harmony with the requirements is enormously increased

In so far as this is a true reading of the facts, it implies that the apparent Lamarckian effect is nothing but a special case of the Darwinian selection But, whereas Darwin called on unstable random variations to provide the material for natural selection, Mendel, De Vries, Morgan, and others have shown that the new material really consists of stable, true breeding mutants So far from upsetting the Darwinian theory, that emendation makes it more workable , and if to it we add the conception of an early massacre of unsuitable mutants, the tempo of the selective process will be further accelerated

It is possible to imagine still greater speeding up by viewing selection at a different angle The Darwinian regards what he calls Nature—that is, the totality of environment—as the selector But what if we lay the burden of selection on the creature ? No more in this case than in the former is any conscious choice implied An animal with defective pigment and sight will not escape its enemies unless it skulk in dark corners A mutant that can exist only in warmer water than that supported by its parents will perish if it do not find such a habitat Individuals that happen on suitable conditions will be saved

[8] "Examples of suicidal evolution," mostly instances of excessive calcification are well discussed in various works of W D Lang, who has recently given a brief summary, Form in Fossils, *Proc Geol Assoc* , 39, 429-44, January 1929

A population is subject to both kinds of selection Whether the environment of a given locality change or no, the fit among the offspring that remain in it are passively selected by Nature, those that migrate, because uncomfortable, actively, though accidentally, select a fit habitat Thus arises divergence

If the problem of adaptation is brought nearer to solution by these modern extensions of theory, there remain the questions of irreversibility and trends, especially those that seem to us out of harmony with the environment Those phenomena suggest a tendency of mutation to follow the change of environment, and they do so far more than the rare and somewhat doubtful instances in which an experimenter claims to have produced a heritable modification, or a mutant conforming to some modification that he has produced by outer stimuli in the adult parent If, then, we could find some general principle governing mutation, we might approach an explanation of the whole evolutionary process

May I suggest a possible direction of search for such a principle? The evidence thus far available indicates that mutation depends on some physico chemical change in the particles that make up the chromosomes of the male and female germ cells That chromosome particle, or gene, on which a certain structure of the adult is believed to depend, must have a chemical constitution more complicated than that of any organic compound as yet elucidated by chemists, but the changes in its composition must follow the same laws

The ordinary chemical changes of living substance are reversible, that is a character of life, a compound broken down is at once reformed But certain reactions are irreversible, and conspicuous among them is the whole process of growth and senile decay If, then, some external agent produce a change in the molecular arrangement of a gene, that change may well be irreversible Indeed, the mere removal of the external agent could not be expected to cause a reversal of the reaction Again, just as other irreversible changes in an organism proceed in definite directions, so a succession of changes initiated in a gene would be likely to follow a single line Whether a chemical change consist in the loss of a molecule or in a rearrangement of molecules, it seems that the number of possible changes would become increasingly limited This limitation would, in course of ages, apply to each of the genes

If the changes in the genes were merely random, then the organism would be just as likely to vary in a negative as in a positive direction But if the evidence convinces us that variation is more in a positive direction, then the changes in the genes cannot be random, but must be produced or controlled by some factor external to them

How, precisely, external influences are conveyed to the chromosome particles is another question Some researchers, as J T Cunningham, rely on the action of hormones, internal secretions conveyed by the blood to the germ cells But what happens when the hormones get there? The chromosomes lie in the plasma of the germ cell, and it has long been recognised that this is not without effect on inheritance Now Hirata has recently described a chemical mechanism by which a change in this plasma acts to some extent on the gene At first the influence is manifested in the adult offspring as a non heritable modification, but it is suggested that a continuance and intensification of the stimulus might be so firmly impressed on the gene that the change would be passed on to the offspring Thus the modification would become a mutant, and our problem would to that extent be solved

I have attempted to keep my speculations consistent with recent work in genetics and bio chemistry If some such physico chemical structure be admitted as the basis of variation, and if the irreversibility of the chemical changes in it be allowed, then it seems to provide that fundamental premise from which, in combination with a varying environment, one can deduce irreversibility of evolution, reduction of variation, and orthogenetic trends The decisive principle is still natural selection, but the material on which selection acts is not supplied at random, it is subject to certain laws, and those laws assist the progress of that evolution of life which is revealed to us by palæontology

Obituary.

DR H BRAUNS

HANS HEINRICH JUSTUS CARL ERNST BRAUNS, who died on Feb 3 at his residence in Willowmore, Cape Province, at the age of seventy-two years, was born in Hannover, Germany, and spent his school-days in Mecklenburg, where he also entered the University, obtaining the Ph D degree He studied medicine at several places, including Göttingen and Leipzig, from which latter university he obtained the M D degree The honorary degree of D Sc was conferred upon him in 1928 by the University of Stellenbosch in recognition of his services to entomology in South Africa He was a member of the Royal Society of South Africa, and shortly before his death was elected an honorary member of the Société des Sciences Naturelles, Musée du Congo Belge, Tervueren

On the completion of his medical studies, Brauns travelled in the East, India, and North, Central, and South America In 1895 he went to South Africa, settling eventually at Willowmore in the Karoo, where he worked until 1925

Brauns collected insects all over South Africa, but mostly from the Karoo His chief interest was centred in Hymenoptera, his collection of which is now in the Transvaal Museum, Pretoria He published numerous papers, memoirs, and monographs on South African Hymenoptera, especially on the Apidæ, Sphegidæ, Masaridæ, and Chrysididæ, and his systematic work on genera such as

Cerceris, *Crocisa*, *Epeolus*, etc, is important He was a keen observer and first class field naturalist, and his many observations on the habits, development, nest building, prey parasites, food plants, and general bionomics of Hymenoptera have earned for him a prominent position as an entomologist He also contributed to our knowledge of termitophilous and myrmecophilous insects His indefatigable spirit prompted him to collect even up to the last, and shortly before his death he published descriptions of new Chrysididæ

THOMAS OWEN BOSWORTH, who died in London on Jan 18 last, was born at Spratton, Northamptonshire, on Mar 28, 1882 He was educated at St John's College, Cambridge, and was on the staff of the Geological Survey of Scotland in the years 1908 and 1909 The remainder of his life was mainly spent abroad as an oilfield geologist In this capacity he travelled extensively in America, ranging from Peru to within the Arctic circle His published works include " The Keuper Marls around Charnwood " (Leicester, 1912), " Geology of the Mid Continent Oilfields, Kansas, Oklahoma, and North Texas " (New York, 1920), " Geology of the Tertiary and Quaternary Periods in the North West Part of Peru " (London, 1922), and several papers in the *Geological Magazine* In the work on Peru, Bosworth gives a fascinating account of the later geological history of the region, and his description of the present conditions and processes in the desert is full of interest to both geologists and geographers By his death at the early age of forty six years, geology has lost a very able investigator

News and Views

THE Soviet Government has now completed the first part of an extensive electrification scheme which was begun almost immediately after the Revolution A large 80,000 h p hydro electric station has been built on the River Volkhov about 80 miles east of Leningrad The power is supplied to Leningrad by overhead lines at 120 kilovolts The Swedish General Electric Co (Asea) supplied most of the equipment and assisted in the planning of the station Metropolitan Vickers Electrical Company of Manchester also supplied some of the equipment In the communication between the generating and distributing station, the transmission lines are used as part of the circuit The communication between the machine room and the control room is by ship's telegraphs According to Reuter (Moscow), the Soviet Government has also started broadcasting, the control of which has been put in the hands of the Commissariat of Posts and Telegraphs In addition to radio technical and agricultural courses, a university has been opened the lectures in which are all given by radio By means of telephone lines, broadcasting is being extended to isolated villages A very rapid increase in the number of radio listeners is expected According to the estimates of the Commissariat, the number of listeners will have increased by a million before the end of this year Radio theatres have been opened in both Moscow and Leningrad and experiments are being made with radio films On Aug 1 next, a new radio station with a power of 75 kilowatts will be opened in Moscow

IN January this year, Dr T A Jaggar, Director of the Hawaiian Volcano Observatory, predicted that an eruption of either Kilauea or Mauna Loa was to be expected during 1929 The prediction, based on the cyclic behaviour of the Hawaiian volcanoes first recognised by Dana, was made good in spectacular fashion on Feb 20 On that day, Washington received the following radiogram " Kilauea flashed into magnificent eruption at 1 00 A M Hawaii time this morning " We learn from a *Daily Science News Bulletin* issued by Science Service of Washington, D C, on Feb 21, that the opening phase began with vast fountains of lava, spurting to heights of two hundred feet from a long crack in the floor of Halemaumau Pit In twelve hours the pit was filled with a lava lake to the depth of sixty feet By that time the fountains were still playing to a height of a hundred feet, and the level of the lava lake was rising at the rate of five feet per hour Driblet cones formed above the effervescent lava, and from the higher jets liquid drops were blown off to fall at first as pumice but later as clear brown glass relatively poor in gas bubbles Quantities of the fine spun glassy threads known as 'Pelé's hair' have been formed by wind action from the crests of the waves of molten rock The seismograph at Volcano House records a constant tremor, and an inclination from the vertical away from Halemaumau Pit Since the eruption started, constant additions have been pouring into the cauldron as a result of landslides of volcanic detritus from the steep slopes of the sides It is anticipated that the present phase of intense activity will continue for several weeks

MR R A WATSON WATT delivered the Symons Memorial Lecture of the Royal Meteorological Society on Mar 20, taking as his subject " Weather and Wireless " Mr Watson Watt stated that wireless as a means of communication is essential in modern meteorology because it alone is capable of giving sufficiently rapid interchanges of data over wide areas The results of observations made all over Great Britain are in the hands of the central forecaster within an hour, the majority of the data for Europe are received within an hour and a half, and that for the whole Northern Hemisphere within six hours It was announced that an experimental transmission from Daventry of daily weather charts is to commence shortly Wireless has a 'climate' and a 'weather' of its own The weakening of signals over different kinds of country, according to time of day and season, and the dependence of atmospheric disturbance on latitude, place, and time, are climatological in scope The quick period changes, the erratic phenomena of fading, are part of the 'weather' of wireless—atmospherics are its 'rainfall'

MR. WATSON WATT stated that the average atmospheric is a hundred thousand times as strong as a readable signal. They have been known to disturb broadcast reception up to four thousand miles from their place of origin. They originate in thunderstorms and the predominant source of the world's supply of atmospherics at any moment usually lies in a land where it is summer afternoon. The average atmospheric received in England is of such strength as would be sent out by a thunderstorm 2000 miles away. Speaking of the alleged effects of wireless on weather, Mr. Watson Watt stated that the average rainfall of England requires for its production the expenditure of energy at the rate of a third of a million horse power per square mile, night and day throughout the year. The total rate of emission of energy from all the broadcasting stations of Great Britain and Northern Ireland, in the limited periods during which they work, is less than 55 horse power. Any effect of broadcasting on weather would therefore be due to 'sub homeopathic doses' of less than one in a thousand million. The lecture was illustrated by the reception of current weather maps and written forecasts on the Fultograph system, and by demonstrations of the cathode ray direction finder, a visual direct reading instrument used for locating wireless transmitters and thunderstorms.

IN his Friday evening discourse, delivered on Mar. 22 at the Royal Institution, Sir Ernest Rutherford dealt with "Penetrating Radiations." There exists in our atmosphere a type of ultra penetrating rays often called the cosmic rays of about a hundred times the penetrating power of gamma rays. The frequency of vibration of these cosmic rays is from a hundred to a thousand million times greater than that of ordinary light. For ordinary X rays, the quantum of radiation, in passing through the atoms of matter, occasionally interacts with one of the component electrons and the whole wave energy of the quantum is given to the electron, which is set in rapid motion and ionises the matter in its path. The chance of such a conversion of the energy of the radiation, called the photoelectric effect, increases rapidly with the weight of the atom and falls off markedly as the frequency of the radiation is raised. Another process, called scatterings, is also always present. The effect is small for ordinary X rays, but becomes predominant for very high frequency rays. In this process, called the Compton effect, the radiation is scattered and at the same time the electron is set in motion. The scattered radiation is degraded in frequency in amount depending on the angle of scattering. In very penetrating rays, the average frequency of the scattered wave is reduced to about one half for each scattering collision, when about half the energy in the average is given to the recoil electron. Consequently, when a very penetrating radiation passes through matter, recoil electrons of high speed, and degraded radiations, are always present. The experimental information is at present too scanty to fix with certainty the origin and nature of these penetrating rays. It has been suggested that they come from outer space, and represent radiations which arise in the destruction or creation of atoms. The energy of the quantum in the most penetrating radiation measured by Millikan is of the order of 1000 million volts. It may prove significant that radiation of this energy may be expected to arise if the proton can be converted into radiation by a single catastrophic process.

THE Medical Research Council has lately issued three important monographs in the Special Report Series (H.M. Stationery Office). No. 124, by E. G. D. Murray, gives a critical account of the general biology of the meningococcus, the causative micro organism of cerebro spinal fever. No. 125, by Hugh Cairns, is a study of intra cranial surgery, based upon a year's residence as assistant surgeon in Dr. Harvey Cushing's clinic at Boston, U.S.A. The medical reader, even, will be astonished at what can now be accomplished in this branch of surgery, and it is remarked that, apart from the difficulties of diagnosis and surgical approach, the brain is just as amenable to surgery as are the peripheral nerves. No. 126 contains a summary of reports for 1927 from research centres in Great Britain and Ireland on the medical uses of radium. There can now be no doubt that radium is a valuable adjunct, properly applied, in the treatment of cancers. Some inoperable cases are apparently cured, and even when this happy result does not ensue, life is frequently prolonged and the last days of the patient are rendered more comfortable. Much, however, remains to be elucidated as to the proper dosage, and the best method of application, of radium.

THE value of the work carried out at what are termed forest products laboratories is now beyond cavil. The first was established in the United States in Madison, Wisconsin. An important branch of the Research Institute at Dehra Dun, India, is occupied with similar researches, as also a section of the Bureau of Science at Manila in the Philippines. The Forest Products Research Laboratory at Princes Risborough in Great Britain has already been alluded to in NATURE. A pamphlet (No. 9, Melbourne, 1928) has been recently issued in which Mr. A. J. Gibson, a conservator of forests in India, lent to Australia for the purpose of the inquiry, discusses the question of "A Forest Products Laboratory for Australia." Mr. Gibson arrived in Australia in August 1927 and spent four months in visiting all the States of the Commonwealth, his report being based on the results of his investigations. In publishing the report the Council for Scientific and Industrial Research, under the auspices of which the investigation was carried out, states that its publication does not assume 'that the opinions expressed therein are its adopted views nor that it is intended to follow, in their entirety, the recommendations made.'"

As a result of his investigations and tours in which Mr. Gibson acknowledges his indebtedness to the forest and research officers of the various States, he expresses the opinion that the establishment of a central Forest Products Laboratory for the Commonwealth of Australia is advisable. One of the reasons given is a common one, and yet not the less important for that reason. In the past, he says, there has been much overlapping of research work and waste of

money owing to the absence of co ordination between the various States and the Federal Government in this matter He recommends the setting up of a central laboratory, and estimates the rough cost as follows A capital expenditure for erection of buildings and equipment of £49,000, an annual expenditure of £10,400 for the personal staff, and another £8600 for maintenance or a total for personnel and maintenance of £19,000 per annum

VOLUME 2 of the *Bulletin of the Hill Museum* (1928) has recently come to hand The first volume of this publication was completed in 1924, and it is announced that with the commencement of Vol 2 a part will be issued each quarter The journal is devoted to the publication of original papers on Lepidoptera based upon the splendid private collections of Mr J J Joicey, housed in the Hill Museum at Wormley, Surrey Contributions from outside sources are also accepted, provided they deal with collections made for the Hill Museum or are based upon studies carried out there Among the various papers included in this volume, Prof E L Bouvier's finely illustrated account of the Saturniid moths from the East Indies is important on account of the new species and varieties described Mr Arthur Hall's revision of the genus *Phyciodes* and papers by Mr G Talbot (and others) on material from Matto Grosso, Brazil, and the Great Atlas Mountains, are also noteworthy The *Bulletin* is admirably printed, and is illustrated by well executed coloured and other plates The subscription price is 30s per volume, payable to Mr G Talbot at the Hill Museum it is also announced that the *Bulletin* will be sent in exchange for other publications on Lepidoptera

A SEVERE earthquake, that must have shaken a wide area in British Columbia and southern Alaska, occurred on Mar 1 at 2 31 A M (Eastern Standard Time) The epicentre is placed by the seismological section of the U S Coast and Geodetic Survey in lat 53° N, long 122° W, or in the strait between Queen Charlotte Island and the mainland An after shock, almost as strong as the first, occurred in the same place a little more than an hour later (*Daily Science News Bulletin*, Science Service, Washington, D C The epicentre of both shocks lies about 160 miles south east of that of the Alaskan earthquake of Oct 24, 1927, which was probably situated near Wrangell and Juneau in the narrow sounds of the Alexander Archipelago (NATURE, vol 120, p 667) The central areas of the two earthquakes thus seem to occupy a submarine band parallel and close to the western coast of North America.

UNTIL comparatively recent years, earthworms have been regarded as entirely useful animals, as they benefit the agriculturist by opening up the subsoil and improving the general condition of the land, and also they provide a prolific source of bait for inland fishing Under modern conditions, however, they are a nuisance on lawns and golf courses on account of the mounds of earth they build up at the entrance to their burrows, which are unsightly and interfere with play in golf W R Walton (*Farmers Bull*, No 1569, U S Dept Agric) epitomises our present knowledge of the life history and habits of earthworms, indicating the chief species that are of economic importance Earthworms are a favourite food of wild song birds and domestic poultry In the latter connexion it should be noted that the eggs or larvæ of the gape-worm are swallowed by earthworms, and if in their turn these are eaten by chickens, the latter may contract the disease of gapes, for which the mortality is very high among young birds The collection, storing, and rearing of earthworms for sale is a regular industry in fishing areas, and methods used in connexion therewith are described When it is desirable to reduce earthworms, as on lawns and golf courses, various vermicides may be utilised, including corrosive sublimate, ammonium sulphate, powdered arsenate of lead, and mowrah meal In flower pots and flower beds saturated limewater applied freely to the soil will destroy earthworms and not injure the plants

AT the end of the third volume of the *Quarterly Review of Biology* (December 1928) the editor, Prof Raymond Pearl, reports on the cost of the biological books received during the year 1928 These books are classified by origin—United States, Germany, English American (that is, published in England and imported by a branch in America), England, France, other countries In the last named group two expensive books with many plates should be omitted before taking the average price Leaving these two books out of the reckoning, Germany heads the list—the price per page working out at 1 48 cents, the English American at 1 46, British Government publications 1 26, United States 1 14, England 1 09, France 0 45, and United States Government publications 0 21 cents per page Prof Pearl states that the sample of British Government publications was small and does not give an entirely fair representation of the case He points out the low cost of the U S Government publications, and that French scientific books are still marvellously cheap as compared with the commercially published books of the rest of the world There has been a slight fall (4·4 per cent) in the cost of biological books produced in England as compared with 1927, but the German books received were 23 3 per cent higher in cost in 1928 than in 1927, and 35 8 per cent higher than in 1926 The corresponding increases in the price of French biological books were 25 0 and 28 6 per cent, but the absolute price is so low that the increases are scarcely significant Prof Pearl interprets the feelings of many biologists in Great Britain when he states that it is a question whether the German "publishers are not dangerously close to the point in their pricing of scientific books where they will bring into operation that other sad economic law of which the effect is that absolute returns diminish. There can be no great profit in publishing books at such high prices that nobody buys them."

IN accordance with the recommendations of the recent Committee on the organisation of a Colonial Agricultural Service and of the Colonial Veterinary Services Committee, the Secretary of State for the

Colonies has appointed the following Colonial Advisory Council of Agriculture and Animal Health: Mr W Ormsby Gore (temporarily chairman), Mr F A Stockdale (vice chairman), Lieutenant General Sir William Furse, Dr A W Hill, Dr G K Marshall, Dr E J Butler, Prof T B Wood, Dr W H Andrews, Dr A T Stanton, and Mr R V Vernon The Lawes Trust Committee and the Joint Committee on Research in Animal Nutrition of the University of Aberdeen and the North of Scotland College of Agriculture, respectively, have been invited to give their consent to Sir John Russell and Dr J B Orr serving on the Council Mr G H Creasy, of the Colonial Office, has been appointed secretary to the Council No terms of reference have been given, but the Council s functions will be generally those recommended by the Committees named above

THE International Council for the Exploration of the Sea will hold its annual meeting this year in London on April 8 15 Fifteen countries are now represented on it, namely, Belgium Denmark, France, Finland, Germany, Great Britain, Holland, Irish Free State, Italy, Latvia, Norway, Poland Portugal, Spain, and Sweden The headquarters of the Council are in Copenhagen, and it is there that the annual meetings are normally held The Council last met in London in 1920 when it first reassembled after the War On April 12 and 13 special meetings will be held, by the courtesy of the Zoological Society of London, in the Society s meeting rooms, for the discussion of the fluctuations of fisheries and methods of measuring currents On April 17 a joint meeting with the Challenger Society will be held at the station of the Marine Biological Association at Plymouth

A SECTIONAL meeting of the World Power Conference on the 'Complete Utilisation of Water Power Resources will be held at Barcelona on May 15–23, at the same time as the Barcelona Fair It will be followed by visits to places of interest in Spain The meeting is being organised by the Spanish National Committee of the World Power Conference, with the official co operation of the Spanish Government The subjects to be dealt with are general hydrological problems, technical problems of water power utilisation, economic and financial problems, legal problems, protective measures and defence works of undertakings Copies of the technical programme (in English, Spanish, French, and German) with forms of application for membership, can be obtained from The Secretary, International Executive Council, Central Office, World Power Conference, 63 Lincoln s Inn Fields, London, W C 2

THE unique collection made by Mr and Mrs A C Bossom of the crafts of the Indians of British Columbia has been loaned to the Imperial Institute, South Kensington, S W 7, for display during the period Mar 27–May 20 The British Columbia Indian or Siwash is a mixture of the Mongoloids and Red Indians, and this heredity appears in his art, as some of it is similar to that of the Chinese and Japanese. His artistic instinct is more highly developed than that of the Red Indian, because he is a house dweller and not nomadic The exhibits consist of about 1500 articles, illustrating workmanship in wood, metal, bone, ivory, leather, basketry, etc It is a curious fact that these Indians had no pottery The exhibition is open daily on week days from 10 A M to 5 P M and from 2 30 to 6 P M on Sundays Admission is free

THE proceeds of the Daniel Pidgeon Fund for the year 1929 of the Geological Society of London have been awarded to Mr J Selwyn Turner who proposes to investigate the faunal succession in the Coomhoola Grits and Carboniferous Slate of County Cork

AT the annual general meeting of the Geological Society of London the following officers were elected *President* Prof J W Gregory, *Vice Presidents* Dr F A Bather Prof E J Garwood, Dr E Greenly and Mr H W Monckton *Secretaries* Mr W Campbell Smith and Prof W T Gordon *Foreign Secretary* Sir Arthur Smith Woodward *Treasurer* Mr F N Ashcroft

MOTIONS on the subject of nomenclature for consideration by the fifth International Botanical Congress to be held at Cambridge in 1930, should be in the hand of the rapporteur général Dr John Briquet, before Sept 30 next Further information on the programme of work on nomenclature can be obtained from Dr Briquet, Conservatoire botanique Geneva, Switzerland

THE Ministry of Agriculture and Fisheries has issued anew the Leaflet (No 138) on fowl pox which has been re written It gives a complete summary of the features of the disease and its treatment with illustrations The Ministry also carries out veterinary tests for poultry diseases a charge of 3s being made for a post mortem examination and 10s for a complete examination in outbreaks of bacillary white diarrhœa

IN our issue of Dec 1 1928 p 860 an account was given of the Kimberley meeting of the South African Association for the Advancement of Science held on June 29 July 4, 1928 The full report of the meeting has now been issued (Johannesburg South African Association for the Advancement of Science 30s net) In addition to the presidential addresses the volume contains all the papers recommended for publication after presentation at the meeting There are author and subject indexes

EVERY scientific worker must have had the experience of being asked to recommend for popular reading a book in some branch of his own science, and of being hard put to it to find a satisfactory answer The Committee of the Leeds Public Libraries has got over the difficulty by inviting experts to compile, with suitable comments, lists of works dealing with all the aspects of various subjects of popular appeal The lists are published as small booklets at a price of 3d each, and are suggestive library guides In the scientific series the latest to appear are "What to Read in Zoology" by Prof J Arthur Thomson, and "What to Read in Biology" by Prof W J Dakin

MESSRS W Heffer and Sons, Ltd, Cambridge, have just issued a catalogue (No 323) of some 1800 works dealing with agriculture, botany, zoology and biology, chemistry and chemical technology, medicine and physiology, mathematics and physics, including long runs of publications of the learned and scientific societies The list can be had free from the publishers

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A temporary zoological assistant for work on the zoological collections of the *Discovery*—The Secretary, *Discovery* Committee, Colonial Office, Whitehall, S W 1 (April 7) A full time lecturer on electrical engineering at the Leicester College of Technology—The Registrar, College of Technology, Leicester (April 8) A demonstrator in the department of chemistry as applied to hygiene, at the London School of Hygiene and Tropical Medicine—The Secretary of the School, Malet Street, W C 1 (April 10) A physics tutor at the University Correspondence College—The U C C, Burlington House, Cambridge (April 12) A junior assistant under the Air Ministry, with good general technical knowledge of wireless ground stations, directional wireless and wireless in aircraft, and of development of short wave wireless telegraphy and telephony especially in its use in aircraft—The Secretary, Air Ministry (S 1), Adastral House, Kingsway, W C 2 (April 15) An assistant curator in the Royal Botanic Gardens, Kew—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S W 1 (April 15) A principal of the Shoreditch Technical Institute—The Education Officer (T 1a), The County Hall, Westminster Bridge, S E 1 (April 16) A principal of the Hackney Technical Institute—The Education Officer (T 1a), The County Hall, Westminster Bridge, S E 1 (April 16) An inspector of ancient monuments for Wales—The Chief Inspector of Ancient Monuments, H M Office of Works, Westminster, S W 1 (April 21) A chief inspector of the West Riding of Yorkshire Rivers Board—H F Atter, 71 Northgate, Wakefield (April 30) An independent lecturer in economics at the University College of North Wales—The Registrar, University College of North Wales, Bangor (May 13) An advisory dairy bacteriologist at the Harper Adams Agricultural College—The Principal, Harper Adams Agricultural College, Newport, Salop

Our Astronomical Column

AURORAL ARCS ON MAR 14 AND 16 —Auroral arcs were seen on Mar 14 and 16 at 7 P M by Prof H Bassett and Mr R G Durrant and by several other spectators at Reading On both occasions the phenomenon presented itself in precisely the same position, but it was fainter on Mar 16, the moon's light being stronger The altitude of the brighter part of the arc was approximately 30° above the horizon and its breadth about half a degree The arc stretched over an expanse from south south east to north north west or 180° It passed below Venus, the moon, and Jupiter on one side, and between two bright stars at a considerable distance on the other Mr Durrant refers to the event as being an apparition of the zodiacal light, but the aspect of the latter is usually that of a glow in the shape of a cone He alludes to Sir John Herschel's suggestion that the zodiacal light represents a denser region of planetary material consisting of the tails of comets, while Lord Kelvin considered it as the reflected light from a cloud of meteors revolving round the sun There is very little if any distinction between these views Mr Durrant remarks that if the theory just mentioned still meets with acceptance, this solar crape ring must circulate just within the path of Venus, but the object witnessed in the sky at the middle of March seems to have been consistent with that of an aurora

RECENT SOLAR ACTIVITY —A large metallic prominence was observed by Mr Newbegin at Worthing on Mar 18 at the sun's west limb He states that the prominence consisted of delicate filaments in a series of interlacing arches culminating in a dense mass at the top which was 105″ in height This part was dense in helium (D_3) The observation is of interest because it seems likely that this prominence was connected with the disturbed area embracing the large sunspot described as No 4 in NATURE of Mar 16, p 425 (for Mar 5—date when first seen—read Mar 4) On Mar 11–13 a considerable magnetic disturbance took place, the measured ranges at the Greenwich station at Abinger being 47′ in declination and 300γ in horizontal force The storm began with a very pronounced 'sudden commencement' at 13 9 hr on Mar 11 the large leader spot crossed the sun's central meridian about 20 hours earlier

ANOTHER MINIATURE MAGELLANIC CLOUD —Dr W Baade contributes to *Astr Nach*, 5612, a note on the nebulous object N G C II 1613, the position of which for 1900 0 is 0^h 58 0^m + 1° 25, near 26 Ceti It was found by Prof M Wolf from photographs with the Bruce telescope, and described by him in *Mon Not Roy Ast Soc*, 69, p 91, as a faint nebulous cloud, 30′ by 40 in size, with brighter condensations embedded in it He suggested that it was a cluster of small planetary nebulæ An exposure by Prof H D Curtis with the Crossley reflector did not lead to any decisive result Dr Baade has now taken several photographs with the Bergedorf reflector, with exposures ranging from 50^m to 120^m He describes it as a star cloud of the type of the Magellanic clouds, the longer exposure gives its dimensions as 14′ × 12′, the brightest stars in it are of mag 17 to 18 It appears to resemble N G C 6822, a photograph of this by Dr E P Hubble is reproduced in "Astronomy," by Russell, Dugan, and Stewart, p 804 (1927)

THE LIGHT CURVE OF NOVA TAURI, 1927 —*Astr Nach*, 5613, contains a table and diagram showing the changes in the light of this star, which was discovered at Bergedorf on Nov 18, 1927, by Prof Schwassmann and Dr Wachmann, being then of mag 9 5

The Harvard plates enabled the history of the star to be carried two months further back It was invisible (fainter than 11^m 7) on Sept 11, 8^m 2 on Sept 25, 6^m 0 (maximum) on Sept 30, it sank fairly rapidly to 13^m 5 at the end of the year, there was then a slight revival to 12 5 in March 1928 13 5 was again reached in mid April, after which the star was lost in the sunlight An exposure on Aug 28, 1928, with 30 minutes exposure, gave the magnitude 14 4

The light curve gives no evidence of the rapid oscillations of brightness which were such a conspicuous feature in Nova Persei 1901 a few weeks after the maximum

Research Items

NAGA CUSTOMS —Owing to head hunting troubles in 1923 it became necessary for Mr J H Hutton to make two tours to parts of the Naga Hills not hitherto visited by white men One journey was made in April, the second in October Mr Hutton has published a diary of the two tours as No 1, vol 11, of the *Memoirs of the Asiatic Society of Bengal* Many types of implements, utensils, and weapons entirely new to the author were recorded, also new data relating to the burial and head customs, forms of tatoo, etc, as well as much information supplementary to that noted by the authors of the various monographs on the Naga tribes published by the Assam Government In connexion with the Yungya custom of disposing of the dead in trees, the head being afterwards removed, the sacred tree in question is the *Ficus*, for which some veneration is consistently shown among the Nagas Among the Wa of Burma and the Dusun of Borneo it is the head tree The Mafulu of New Guinea use it much as the Yungya, and the Papuan tribes reverenced it Women in southern India who desire children pay reverence to it, and the Akikuyu of East Africa regard it as the abode of the souls of the dead It is, therefore, suggested that the beliefs about, and veneration for, the fig tree may be a negroid cult spread all over the Indian Ocean which has grown up into Hinduism from below Similarly, a negroid belief may survive in the custom of hanging the combs of bees and wasps in the entrance of houses, a custom witnessed everywhere on the first tour A similar custom is recorded in the Andaman Islands and in the Malay Peninsula Its occurrence in the Andaman Islands certainly suggests a negrito origin

THE PURPOSES OF THE PECTEN IN THE EYE OF BIRDS —In the Doyne Memorial Lecture for 1928, Prof Arthur Thomson discussed the functions of the pecten in the light of certain experiments carried out by him He suggests that this curious structure serves other purposes than the nutrition of the vitreous humour and retina and possibly the regulation of inter ocular pressure Its pigmentation, position, and structure, all suggest that it may act as a dark mirror which reflects as well as absorbs light Rays of light, which in the normal position of a bird's head fall upon the pecten from the zenith, have been shown by experiment to be reflected from it, and can be projected upon some sentient part of the fundus, with the great advantage that, so reflected from a dark mirror, they are deprived of the dazzle and glare of bright sunshine and produce a more defined and detailed image The biological advantage of such a device is obvious, for it means that a bird of prey hovering overhead can be seen even against the sun, and the position of the pecten is such that the threatened victim can fly in another direction whilst still 'keeping an eye' on the source of danger The projection of *two* images upon the fundus may enable birds to estimate distance more accurately, a valuable power where dense foliage has to be traversed at speed Though the pecten in birds is built upon a general plan, it shows remarkable variations in size and form, and these are characteristic of different species

BIOLOGY OF THE BAY OF PETER THE GREAT (SEA OF JAPAN) —The curious peculiarity of the Bay, according to G U Lindenberg (*Priroda*, No 11), is the fact that its fauna is similar in its character to the terrestrial fauna of the Ussuri region. Even the first explorers of Ussuri noted the mixture of such typically northern forms as the fir and cedar, the sable and the arctic deer, with such typical southern forms as the American vine and the Manchurian walnut, tiger and the racoon like dog This is analogous with the aquatic fauna of Peter the Great Bay The conditions which gave rise to this peculiarity are not the same in the cases of the terrestrial and the aquatic fauna The climatic conditions of the great ice age played an important part in determining the character of the terrestrial flora and fauna, whilst the aquatic fauna is greatly influenced by the hydrological regime of the Sea of Japan The occurrence of series of southern forms in the bay during the last three years may be partly explained by hydrological changes of the regime of the bay It cannot be denied, however, that the southern forms were overlooked by previous explorers Such typical representatives of the northern fauna as cod (*Gadus callarias macrocephalus*) and dorse (*Eleginus navaga gracilis*) are found among the fishes of the bay At the same time, many of the southern forms, such as the herring, *Chirocentrus dorab, Sphyrna zygæna, Alectis ciliaris, Priacenthus hamrus*, and others are found in the bay The sword fish, *Trichiurus Japonicus*, the flying fish, *Cypselurus agoo, Stromateoides echinogaster, Hemirhamphidæ, Scombresocidæ, Belonidæ, Mugilidæ, Scombridæ, Monacanthidæ, Tetrodontidæ, Triglidæ, Echeneidæ, Gobiidæ*, and other representatives of southern seas are numerous So far as is known at present, the fish fauna of the Bay of Peter the Great consists of 233 species, belonging to 53 families Quantitatively, the fish fauna is richer than that of other Russian seas, such as the Black Sea, the Baltic, the Arctic Ocean, etc The character of the fish fauna of the Bay of Peter the Great is nearer to that of northern Japan and Korea than to the Okhotsk and the Bering seas

TWO NEW HYDROIDS —A E Briggs describes (*Records Australian Mus*, 16, 1928) two new species of the hydroid genus *Myriothela* collected near Sydney, New South Wales Six species of the genus are known from northern seas and one from antarctic or subantarctic waters The discovery of these two new species considerably extends the known range of distribution of the genus *M australis* was found attached to seaweed thrown up on the beach and may prove to be a shallow water species The specimens range in length from 4 mm to 30 mm *M harrisoni* was found on the under surface of rocks below the level of low spring tides A large number of capitate tentacles is present--up to 1500 in *australis* and up to 600 in *harrisoni* In both species the gonophores borne by one individual are of the same sex Both male and female gonophores have an apical opening representing the velar aperture The salient structural features of *M australis* are described

LEAF FALL IN FROST —It is well known that frost may cause a premature leaf fall, but the relation of this phenomenon to the normal process, in which leaf fall is preceded by the differentiation of a special absciss layer, has seldom been followed in detail Studies of this nature have recently been carried out by Dr Anton Mühldorf, who, in addition to observations in the field in the autumn, exposed plants at various stages of development to freezing temperatures which were produced artificially An account of this work appears in the *Bulletinul Facultatii de Stiinte din Cernauti*, vol 2, pp 267 304, 1928 Briefly, his conclusion is that this leaf fall is a special case of the normal process of leaf abscission, in which the actual separation of the leaf is accelerated as the

result of the changes set in motion by freezing For example, sap is released into the intercellular spaces where its subsequent expansion on freezing facilitates the separation of the cell walls in the region where abscission takes place If, however, leaves have not yet commenced to differentiate the usual specialised abscission layer at the time when they are exposed to frost, they die and decay on the plant and do not fall off before decaying Dr Muhldorf notes that the vacuole sap released by the cell at the moment of death by freezing has a weakly acid reaction, and this may favour the subsequent hydrolysis of the middle lamella, but this factor alone is quite in operative in producing leaf fall unless the usual abscis zone is already differentiated This paper contains a very full discussion of the general phe nomena of leaf fall accompanied by an extensive bibliography in which, however, British and American work is not cited

Coal in South Africa —The Geological Survey of the Union of South Africa has published the third volume of "The Coal Resources of the Union of South Africa" as *Memoir* No 19 of the Survey The first volume contained descriptions of the coalfields of Witbank, Springs, and Heidelberg, and of the Orange Free State, the second volume described the inland coalfields of Natal, and the present volume deals with such of the coal bearing areas of the Transvaal as were not described in Vol 1, together with the coal-fields of the Cape Province The Transvaal area here described comprises the Eastern Witbank coal field, the Bethal coalfield, the Ermelo and Middelburg-Belfast coalfields, the Piet Retief Wakkerstroom coalfield, and a number of less important fields, such as Springbok Flats, Northern Waterberg, Zoutpans berg, and Komatipoort The Cape coalfields appear to be of but little importance, the only area in which coal has been worked to any extent is the Stormberg area, but even here the coal is of inferior quality and the seams are thin and much intermixed with shale bands, so that competition with the Transvaal and Natal coalfields is practically out of the question, and the author of the memoir, W J Wybergh, states that although there are actually many million tons of coal in existence in the Stormberg coalfield, it is highly improbable that it will ever be economically possible to work it apart from very unimportant local require ments The important Transvaal coalfields are fully described, the quantities of coal reserves are carefully estimated and numerous analyses are given, so that the present volume may be looked upon as satis factorily completing the information contained in the two previous volumes on South African coal resources

Palæozoic Insects —The meagre but interesting fauna of the Rhynie chert found in the Old Red Sandstone of Aberdeenshire comprises a minute branchiopod crustacean (*Lepidocaris*) allied to the *Anostraca* (Nature, **118**, p 89, 1926), some arachnids, including the only true mite known in the Palæozoic, and the remains of some minute insects—the only insects known in rocks of earlier date than the Upper Carboniferous These insects, which were first de scribed by Hirst and Maulik, have been re examined by Dr R J Tillyard (*Trans Entomol Soc London*, p 65, 1928), who notes the resemblance of the mandible and antenna to those characteristic of the order Collembola, especially to the family Poduridæ, and concludes that they either belong to that order or are ancestral to it From comparative morphology it is inferred that the primitive Thysanura must also have been in existence in Devonian times The specimens consist of four more or less perfect heads for which the genus *Rhyniella* was established by Hirst and Maulik, and some jaw like structures for which the generic name *Rhyniognatha* is used In part 10 of his series of papers on Kansas Permian insects, Dr Tillyard (*Amer Jour Sci* (5), **16**, p 185, 1928) gives a detailed account of the genus *Lemmatophora*, this has hitherto been referred to the order Protorthoptera, but is now shown to be related to the recent order Perlaria (stone flies), and is taken as the type of a new order, the Protoperlaria The wing of a damselfly (genus *Permagrion*) from the Upper Permian of the Falkland Islands has been studied by Dr Tillyard (*Trans Entomol Soc*, p 55, 1928) It is the oldest known type which can be definitely referred to the sub order Zygoptera of the order Odonata (dragonflies), and is allied to the more primitive form *Kennedya* from the Lower Permian of Kansas The evolution of the order Odonata in Palæozoic times is discussed by Dr Tillyard (*Rec Indian Mus*, **30**, 151, 1928) The characters of the two related orders Protodonata and Odonata are analysed, and it is concluded that the common ancestor is to be found in the Westphalian genus *Brodia* of the order Megasecoptera The evolution of the Odonata in Mesozoic and Tertiary times will be dealt with in the second part of the paper

Ultrasonic Radiation —In the February issue of the *Journal of the American Chemical Society*, Schmitt, Johnson, and Olson describe further experiments on the chemical action of very intense sound waves Iodine is liberated from a solution of potassium iodide, probably owing to the intermediate formation of hydrogen peroxide, since a reaction was obtained when a titanium sulphate solution was irradiated Solutions containing hydrogen sulphide and air be come strongly opalescent after exposure for a few minutes, owing to liberation of sulphur

Earth Current Registration —Dr S K Banerji, Director of the Bombay Observatory, informs us in a recent communication that he has succeeded in register-ing earth currents with lines only 250 yards long, whereas usually lines of some miles in length are employed, in order to minimise polarisation effects at the electrodes He overcomes polarisation difficulties by making the electrodes neutral with respect to the soil, each elec trode being a combination of electropositive and electro-negative metals, the actual composition being found by trial, and varying with the soil The neutrality is not maintained indefinitely, and to avoid frequent removal and scraping of the electrodes, small separate electrodes of the positive and negative metals are sunk, and one or other of these is joined to the main as and when found necessary to correct for any small polarisation current that may develop Such in stallations have been set up at Colaba and Alibag, which are about 15 miles apart, and about 5 and 18 miles respectively from the centre of the Bombay electric railway network Photographic records of the earth currents show the leakage from this network, the oscillations are in excellent agreement with the voltage record at the power station The amplitude of the oscillations of the leakage current is about 110 microamperes at Colaba, and only 5 at Alibag, the reduction in amplitude agrees roughly with that corresponding to laminar flow A plane current sheet of even 5 microamperes is sufficient to disturb the magnetic registers very appreciably Besides the leakage currents, the earth current records show the natural diurnal current variation, and disturb ance currents during magnetic storms

Chemotherapy with Lead Compounds —It is now some years since Prof Blair Bell first published in the

Lancet an account of the use of lead in the treatment of malignant tumours, and his work has attracted a considerable amount of attention Another question which has also been discussed recently is that of the toxicity of organic compounds of lead, for example, lead tetraethyl These two fields of inquiry have lately been combined in an investigation which has been carried out on the chemical side by Dr Erich Krause, of the Technische Hochschule, Berlin, who contributes a paper to the January number of the *Berichte* (vol 62, pp 135 137), and on the pathological side by Dr W A Collier Various organic compounds of lead (and also of tin) are worked into emulsions with a gum arabic solution, and are injected into the necks of mice The tolerated dose of substances applied in this way varies considerably, and does not appear to depend on the solubility Thus triphenyl lead fluoride or triphenyl tin bromide is fifty times as poisonous as diphenyl lead dibromide Aliphatic and hydroaromatic lead compounds are among the less toxic substances, and are therefore used in the treatment of experimental cancer A carcinoma emulsion is injected into mice, after which half the animals are treated once with lead compounds as above The results indicate definite curative effects, the treatment either preventing the development of tumours, or causing tumours to heal after partial development The most effective substances are found to be tri normal propyl lead fluoride, or the less toxic tri iso butyl lead bromide, and lead tetraphenyl and tri cyclohexyl

AUTOMATIC RECTIFIER SUBSTATIONS — Recent statistics show that the owners of railway and tramway systems and lighting and power networks are adopting the policy of making their substations completely automatic This movement began in America, where the need of highly efficient plant is felt very acutely In Europe the economic conditions involve the factors of high labour costs, the eight hour day, and the necessity of safeguarding the workman in the best possible way In the *Brown Boveri Review* for February, a full account is given of the automatic substations this firm has installed for the Brno tramway company in Czechoslovakia Instead of using rotary converters and complicated combinations of standard relays, mercury arc rectifiers are used These are of robust construction In order to connect the rectifier set with the network, it is merely necessary to close two switches When working with rotary converters it is necessary to synchronise the machines and also verify that the polarity has not been reversed after every operation The vacuum in a rectifier is maintained by a pump set which is started working or shut down according to the value of the vapour pressure in the rectifier A time switch automatically closes the circuit breakers This is the first step in operating the substation By means of a remote controlled switch in the distant central power station, the plant is started up or shut down Should the load become excessive, a thermal relay automatically puts the reserve set into operation All the control gear is kept in cases which are sealed and completely dust tight The average daily efficiency of the rectifier substations is stated to be 92 3 per cent This compares with an efficiency of 87 6 per cent for a rotary converter station A brief inspection of these plants is made once a week and their working is controlled in detail every month

PHOTO CELLS —Great progress has been made recently in the development of photoelectric cells or, as they are now more commonly called, photo cells Compared with selenium cells, they are much more trustworthy and consistent, unlike them, their response to variations on the light falling on them is practically instantaneous They have numerous practical applications Most systems of 'talking films,' for example, use these cells, so as to convert varying light impulses into electrical currents which are applied and reproduced as synchronised sound in loud speakers in the cinema Another application of importance commercially is to picture telegraphy Variations of light falling on the photo cell cause electric currents which can be transmitted by land lines and cables and radio, and are then converted into varying light impulses which are recorded on sensitised photographic paper In the February number of the *Osram G E C Bulletin*, the principles of the action of this new development are given The action of the valve depends on the emission of electrons from a suitably prepared metallic surface when light falls on it The photoelectric currents are extremely small, being of the order of one microampere even with strong sources of illumination They have the invaluable property, however, of being proportional to the incident light They can thus be used for most forms of light measurement They can be made sensitive to particular colours, and this enables them to be usefully applied in practical photometry It seems certain that within the next year or two practical photometric measurements will be made by their use Baird uses them in his system of television A special cell can be made which only responds to infra red light invisible to the human eye This can be used as a burglar alarm

A NEW EQUATION OF STATE —Paper 5 of Volume 63 of the *Proceedings of the American Academy of Arts and Sciences* gives an account of a new equation of state for fluids introduced by Drs J A Beattie and O C Bridgeman of the Research Laboratory of Physical Chemistry of the Massachusetts Institute of Technology It is $pV^2 = RT(1-\epsilon)(V+B) - A_0(1-a/V)$ where $B = B_0(1-b/V)$ and $\epsilon = c/VT$, a, b, c are constants and the other symbols have the usual meanings The terms involving A_0 and B_0 represent the effects of the interactions of the molecules of the fluid, while ϵ represents the effects of temperature and density on the time of encounter of the molecules For this equation $(\delta^2 p/\delta T^2)_v$ is always negative but approaches zero at high temperatures and volumes , p approaches RT/V as V increases and $(\delta pV/\delta p)_T$ at low pressures is negative for low and positive for higher temperatures The five available constants of the equation are all readily determined from observed data, and comparisons are made between calculated and observed pressures at 1777 points for ten gases and the average difference only amounts to 0 18 per cent

TANTALUM —An interesting account by G M Dyson of the metallurgy, properties, and uses of tantalum appeared in the issue of *The Chemical Age* for Mar 2 Since its replacement by tungsten for the manufacture of lamp filaments tantalum has been utilised as a substitute for platinum It is unattacked by acids, with the exception of hydrofluoric acid, but reacts with fused alkalis Hence, tantalum cannot always be employed instead of platinum for making chemical apparatus, especially as it is unsuitable for use above red heat, when a superficial oxide film is formed and nitrogen is absorbed Tantalum will absorb all the common gases when heated to a high temperature, and is therefore used in some radio valves since it functions as its own 'getter' and hardens any vacuum in which it is heated Other uses of tantalum are for the manufacture of surgical instruments and for electrodes in electrolytic rectifiers for alternating current

Ultra-Microscopic Viruses infecting Animals and Plants

IN opening the discussion on ultra microscopic viruses infecting animals and plants, held at the Royal Society on Feb 28 and continued on Mar 14, Sir Charles Martin pointed out that the first virus, that of tobacco mosaic, was discovered by Iwanowski, a Russian botanist, in 1892 Five years later, Lœffler and Frosch ascertained that foot and mouth disease of cattle was due to a filter passing contagium, and since that time numerous virus diseases of plants, mammals, birds, insects, and even bacteria have become known These show no common clinical or epidemiological features, and simply form a heterogeneous collection of contagia, all filterable with an infective filtrate and with at present no proved microbial connexion In certain cases distinctive intracellular bodies occur which may be used in diagnosis

Filterability, which gives entry to the group, depends upon numerous and obscure factors Viruses may be good or bad filterers, and this is not simply a question of size That viruses are invisible is merely due to the fact that the finest filters stop particles of about 0 1μ, whilst the limit of microscopic resolution is about 0 2μ The dimensions of virus, probably not less than collargol (20$\mu\mu$), raise the question of the minimum size of living organisms and have suggested the alternative hypothesis that viruses are propagating catalysts Viruses, however, show the characters of living things and there are no essential distinctions save those of size and cultivability Even the latter may be due to a size limitation of their powers of assimilation which renders them obligate parasites, a view supported by the absence of any evidence of saprophytic viruses The study of virus diseases is certainly one of the most important and difficult fields of biology to day

Dr Henderson Smith was prevented by influenza from opening the discussion from the plant side In his communication he emphasised the fact that viruses causing disease in plants are of the same nature as those causing it in animals Some plant viruses attack numerous hosts, whilst others are more narrowly adapted Many viruses can be transmitted by juice or tissue, and these are filterable and highly infective Others can only be transmitted by grafting, and their filterability cannot be determined Probably, in the field, all plant viruses are normally transmitted by insects, in certain cases the relation between a vector and a particular virus is highly specific, and in a few it has been definitely proved that the insect becomes infective only after a period has elapsed since feeding upon a diseased host Such relationships suggest that viruses are some kind of living parasite The intracellular inclusions in certain plant virus diseases give protein reactions but themselves do not seem to be alive The claim that virus disease can be originated *de novo* by inoculation of normal tobacco with normal potato has not been confirmed

Prof P A Murphy emphasised the strong family resemblance between the virus diseases of plants and the difficulties introduced into their study by the fact that many diseases can only be transmitted by grafting or an appropriate insect vector Viruses are not found outside the plant, and there is no good evidence of their culture *in vitro* Fungal and bacterial diseases of plants are local, and the fact that virus diseases are systemic possibly indicates that virus is different in nature from bacteria or fungi Viruses can be attenuated temporarily or permanently, diseases caused are permanent, as a general rule there is no recovery and an attack does not confer immunity Cases of apparent recovery are probably due to the occurrence of carriers, a widespread phenomenon in plant virus diseases

Foot and mouth disease was discussed by Dr J A Arkwright, who said it is notable for its easy filterability and high virulence in dilution The virus is not infectible to other animal species until adapted by passage Infection confers a short immunity, and susceptibility reappears in the same order as the natural susceptibility of different regions in the normal animal During the immune period the blood contains antibodies Foot and mouth vaccine inactivated by formalin confers immunity in guinea pigs and resembles the vaccine of killed bacteria in that the action is proportionate to the dosage The immunity is specific for the three types of foot and mouth and also for the formolised vaccine The properties of the virus do not exclude its bacterial nature, and there is nothing in the available evidence to contradict the idea of its likeness to bacteria The alternative idea of a metabolic product seems unlikely

Mr J E Barnard described some of his efforts to improve microscopic technique, and emphasised the increasing difficulties of observational study as the limits of microscopic resolution are approached His aim is to use light of shorter wave length, which should make it possible to see characteristics of a body smaller than can be seen by visual light A recent development is a dark ground illuminator for ultra violet rays, whereby it is hoped to reduce the exposures to workable limits Mr Barnard showed a number of lantern slides obtained by this method, and in one of bovine pleuropneumonia granules of 0 08μ were clearly revealed He finds that the virus of pleuropneumonia, which consists of vesicles, shows two methods of reproduction, a normal bacillary type and a type quite distinct In his work on this virus he has cultivated two saprophytes of ultramicroscopic dimensions

Experiments on insect transmission of plant viruses were described by Dr Kenneth Smith He thought that the incubation period which had been found in certain vectors might be the time taken for the passage of the virus from the mouth to the salivary juices The virus has no effect on the insect, the period for which vectors remain infective varies with the disease, and two years' experiments have given no evidence of inheritance Lantern slides illustrated his studies of the transmission of potato mosaic to tobacco, and the extraordinary splitting of the virus into a 'needle disease' and an 'aphis disease,' of which the former, but not the latter, may be made lethal to potatoes by rapid transference As an explanation of these 'two' diseases, Dr Kenneth Smith suggests that the sap of tobacco contains a substance which reacts with the saliva of the aphis and so modifies the disease

Dr W E Gye gave an account of his researches on the Rous fowl sarcoma, from which a filter passing virus may easily be obtained capable of producing true tumours giving further infective filtrates There is a group of such filterable tumours of diverse structure showing this power of giving rise to unlimited growth Each gives a filtrate of specific nature The virus shows the properties of other viruses, and its susceptibility to various antiseptics shows the same general range as other organisms, *e g* bacteria In its susceptibility to acriflavine it is similar to pleuropneumonia virus, and it seems of the same order as this virus and also of the same order as visible bacteria.

Prof J C Ledingham opened the second day's

discussion by summing up the impression left on him by the previous contributions, namely, that viruses appear to be like bacteria in most characters save dimensions, that we have not yet exhausted the possibilities of ordinary microscopic vision in the study of viruses, and that one of the most valuable lines of research is the question of virus attenuation in relation to immunisation The importance of the latter is shown in vaccinia and variola, where passage makes feasible vaccination which confers a prolonged immunity With foot and mouth and certain other viruses, the killed virus gives a vaccine conferring a brief immunity but the possibilities of virus attenuation have not been sufficiently exploited in these fields In its attenuation behaviour vaccinia shows inhibitions no different from those of experimental erysipelas, which suggests that the virus resembles visual bacteria No definite opinion can yet be given regarding the nature of the included bodies, which are of uniform size (0 2μ) and behave like staphylococci inoculated under similar conditions Woodruffe and Goodpasture were able to isolate a single body of fowlpox and found it to consist of innumerable elementary bodies Regarding the question of concomitant bacteria, for example, *B suipestis* and swine fever, the action seems to be one of activation of the bacterium by the virus in pigs carrying disease

The more general principles of plant viruses as illustrated in potato mosaic were dealt with by Dr R N Salaman He has been unable to confirm the American results that virus disease may be caused by physiological disturbance due to the introduction of foreign protoplasm into a plant, and thinks that the original results are due to the use of carrier plants Questions of carrying and tolerance underlie all plant studies By inoculation into varieties having different tolerance, it is possible to distinguish viruses producing identical symptoms such as crinkle *A* and *B* Certain viruses, for example, crinkle, are not altered by passage

Prof F W Twort considered that, according to the theory of evolution, we should expect forms of life much more primitive than bacteria, and that such primordial stages might be represented by the viruses Present research methods may not be suitable for the study of such organisms, and entirely new methods are desirable For example, rays below the infra red may be essential to the growth of viruses, and work he has carried out with rays of 21 31 metres wave length has given very promising results

The differences between bacteria and viruses from the immunological point of view were emphasised by Dr C H Andrewes The main character of virus immunity is its solid or absolute character, the condition often lasting throughout life and being related, probably, to the persistence of the virus in the tissues Although viruses inactivated by formalin, etc , confer immunity, it is not possible to immunise or to produce antibodies by heat killed virus In the former case the serum of immune animals contains antibodies different from other known antibodies, and the body's defence against viruses is different from that against visible bacteria

Capt S R Douglas described the electrical behaviour of viruses In all cataphoretic experiments the virus passes to the positive pole The distribution of the virus in the blood in the several stages of certain virus diseases was also referred to briefly

Dr E Hindle gave an account of his experiments on the virus of yellow fever This normally passes moderately coarse filters, but in the mosquito it is arrested even by those of coarsest grain, which suggests the occurrence of an evolutionary process inside the insect's body Dr Hindle thought that the undoubted variability shown by viruses indicated an organismal nature, but the character of the immunity conferred was so different from that in bacterial diseases that virus could not be considered as merely very minute bacteria

Dr W B Brierley emphasised the fact that plant workers give far less value to the character of filter ability than do zoological students In many plant viruses filterability cannot be tested, as the diseases are, under known conditions, not juice transmissible and can only be transferred by grafting or insect vectors Plant viruses exist as numerous strains the virulence of which can in many cases be increased or attenuated Two or more viruses may act in conjunction, producing characteristic diseases which can be analysed and resynthesised experimentally In insect transmitted diseases one insect may carry different viruses or one virus may be carried by different insects, but in certain cases the relationship between virus and insect is amazingly specific, and in at least one case there is a prolonged 'incubation' period The systemic character of virus diseases is not distinctive, certain fungal and possibly bacterial plant diseases being systemic Virus intracellular inclusions have been found in numerous diseased plants, and evidence is accumulating that they are characteristic of particular host virus relationships In spite of certain difficult points such as dimensions, and in the case of animals, immunological characters, a survey of the evidence makes it difficult to visualise the viruses as propagating catalysts or as other than organisms of the same order of life as bacteria

Prof A E Boycott discussed the nature of viruses and briefly summarised views which were published more fully in Nature of Jan 19 He considered that in many ways viruses show the character of ordinary bacteria, whilst in other ways they more resemble the unorganised growth promoting substances and that, as it is all a matter of analogy, which view one accepts depends upon which side one's personal bias tips the scale

A discussion on 'viruses' is rather like what one would expect a discussion on 'insects' or 'bacteria' to be something large and fine, but not a little scattered and diffuse Apart perhaps, from 'the nature of virus,' no coherent thread ran through the contributions The meetings were valuable, however, in bringing together workers from all the fields of virus research and letting them hear and see each other in the flesh.

The Chemical Society in the Industrial North

FOLLOWING the precedent established in 1926, when the annual general meeting and anniversary dinner were held in Manchester, the Chemical Society this year visited Leeds on Mar 21 The proposal to hold such meetings away from London at frequent intervals was one which was immediately commended, the present plan gives many fellows of the Society who for a variety of reasons may find it impossible to travel to London an opportunity of identifying themselves with the activities of the Society, and it also lends an occasion for the greater emphasis, in variously engaged communities, of the part which chemistry plays in modern industry, health, and education, in the modern State, and above all in the world wide development and maintenance of a friendly rivalry in the service of mankind

The official business of the Society was first transacted at a meeting held in the Colour Chemistry Department of the University of Leeds. Afterwards, fellows and others assembled in the Great Hall of the University to receive the presidential address. A cordial welcome was extended to the Society by the Vice-Chancellor (Dr. J. B. Baillie) and by the Lord Mayor of Leeds.

In his presidential address, entitled "Co-operation in Science and Industry," Prof. J. F. Thorpe takes stock of the position in which we find ourselves as a result of the stimulus applied by the War in the direction of scientific achievement, of the developments leading to co-operation in various desirable forms, and of the way in which this stimulus and co-operation are being applied to increase the prosperity of Great Britain. It is, as Prof. Thorpe says, chiefly to the chemical and allied industries that the country turns to increase its productive capacity, its capacity to render available the potential wealth of the nation in a suitable form, whereby alone a universally higher standard of living can be made possible. He is convinced that it is organised industry, relying for its political and financial strength on co-operation—those who hold the keys of national prosperity—who will in the future (if they do not already) call the major chords of the political tune, which is not unreasonable, unjust, or even unlikely, seeing that organised industry both makes it possible to pay the piper and fashions his instrument. By organised industry we suppose Prof. Thorpe to mean the body corporate, composed of capital, and management, and 'labour' (that much abused term, by which we will propose to describe every kind of human service except those accounted for as management and capital)—that body corporate which keeps in the closest possible touch with all sources of new knowledge, with all applications of knowledge both old and new, with human needs, and with national policy.

Four kinds of co-operation, Prof. Thorpe reminds us, are essential to strength: internal co-operation, co-operation with pure science, co-operation with Government, and co-operation with labour. Leaving aside the last, not because of any lack of importance (indeed, this form was described as being "above all" necessary), but merely because the occasion was unsuitable for its discussion, he presents us with an analysis of ways and means, of results and expectations in the domain of the other opportunities for co-operation.

As a concrete example of internal co-operation he selects the common use of hydrogen in three industrial processes: the production of methyl alcohol, of liquid fuels from coal, and of ammonia. Close association of engineers with chemists has been indispensable in order to render possible the establishment of a group of industries so largely dependent on the inauguration and control of reactions under pressure, and on the still empirical employment of chemical 'lubricants,' as catalysts have, not inaptly, been described. There remain, even in the single field of the hydrocarbon industry, vast areas awaiting co-operative exploration. The co-operation required, however, is not exclusively of the strictly scientific kind. Let us suppose that there is a country in the throes of a crisis in its coal-mining industry, yet importing vast quantities of liquid fuel. It is obviously to the advantage of that country literally to liquefy its assets. Science and industry show us that one promising method of producing oils and numerous other valuable raw materials from coal is afforded by the low temperature carbonisation process; but, says Prof. Thorpe, albeit in other and more polished phrases, the unscientific citizens of that country who still burn raw coal on their domestic hearths: no coke, no oil. Again, we are asked to consider the enormous waste of natural gas—millions of cubic feet each day in Canada; twenty-five million cubic feet daily in Persia—and to reflect on what co-operative research might do to utilise it.

Co-operation with pure science is a matter of special moment to our universities, where the human material acquires its knowledge, its impulse, and its outlook, and where opportunities for useful contribution to industrial and national prosperity abound, if only they are made available by support from industrial and national resources. It is, of course, the primary function of the university to attend to fundamentals, both in training and in research; to produce men who are capable of applying their minds with intelligent understanding, with wise vision, with human sympathy, and with appreciation of moral values to the world and its affairs. Prof. Thorpe has special opportunities both to study the inevitable problems and to reach sound conclusions concerning their solution. Discussing the contribution of the universities, so far as co-operation between science and industry are concerned, Prof. Thorpe speaks with experience of the training of the men, pointing out the necessity for research training in order to discover the potential value of a student, and recommending that a higher standard be required of candidates for entry into the honours school. In his remarks on the fundamental research which can be, and is, successfully carried out in the universities, he pays tribute to the far-sighted policy of leading industrial organisations, particularly of Imperial Chemical Industries, Ltd., in affording financial support to enable such studies to be prosecuted under the direction of specialists in various branches of research.

The Government's part in co-operating in science and industry is being exercised in the two most profitable directions in which, in Prof. Thorpe's view, support could be given, namely, on one hand by protection of young and struggling industries, and on the other hand by the promotion of research by means of the establishment of specific inquiry, of financial assistance to industrial groups, and of the provision of research studentships and fellowships. With the present policy of the Department of Scientific and Industrial Research in reducing the number of maintenance grants for students in training Prof. Thorpe expresses dissatisfaction. In fact, he uses words which indicate considerable disquietude: "the outlook is serious"; "it is essential that the State should provide the means for helping to meet this very real national difficulty"; "it is to be hoped that the diminution is merely a temporary expedient." Prof. Thorpe is right in saying that a policy which has provided a steady stream of research workers not otherwise available ought not in any measure to be laid aside while there remains a national need for the best type of research worker. He would be a brave man who would risk his reputation or his roubles in the attempt to prove that the need neither exists in Great Britain to-day, nor is likely to be intensified to-morrow.

In the evening, the anniversary dinner of the Society was held in the Town Hall, the principal guest being Viscount Lascelles, who, in his speech welcoming the Society to the West Riding of Yorkshire, mentioned the special degree to which the prosperity of that part of the country is dependent on co-operation between science and industry. The Lord Mayor of Leeds urged the development of a spirit of collective enterprise, in addition to, rather than instead of, that of private enterprise. The Vice-Chancellor of the University said that the theme of the

address was one which was constantly under discussion in that area it seemed to him that the practical application of science was often more difficult than the fundamental theoretical considerations and he described chemistry as a blend of patience poetry and penetration Prof F Bilmann declared that national feeling is not incompatible with an international spirit in science which is the quintessence of internationality while Prof Max Bodenstein spoke of the common work and the friendship of the workers

Electrical Conductivity in Strong Magnetic Fields

P. KAPITZA has contributed to the *Proceedings of the Royal Society* dated Mar 6 two important papers on the change of the electrical conductivity of metals in strong magnetic fields The first paper is experimental and gives the results of experiments on some thirty five different kinds of metals all of which were subjected to enormous magnetic stresses

In ordinary commercial magnetic testing we rarely go to magnetising forces so high as 50 gauss In Kapitza s experiments the magnetising forces are taken up to 300 000 gauss In order to get consistent results it was found necessary to obtain metals of the greatest purity and to make certain that the metals were all in their normal physical state at the commencement of the experiment Most of the metals were studied at three temperatures at room temperature about 17° C (290° Kelvin) at a temperature of 193° K when the Dewar flask containing the metal under test was filled with a mixture of solid carbon dioxide and ether and finally at a temperature of 88° K when the flask was filled with liquid nitrogen Most of the metals were subjected to both transverse and parallel (longitudinal) magnetic fields

It was found that in all the metals the change of resistance follows the same law which can be expressed by a formula which gives good agreement with the experimental results It shows that in weak fields the resistivity of the metals increases in proportion to the square of the magnetic field but in stronger fields up to 300 kilogauss the increase of resistance is in direct proportion to the magnetic field It is shown that the physical change produced by hardening or annealing the metals has a great effect on the phenomenon of change of resistance in a magnetic field

The experimental results indicate that the resistance can be considered as made up of two components an ideal resistance which is a property of the metal and an additional resistance which is attributed to internal disturbances The ideal resistivity has a constant value for each metal at a given temperature but the additional resistance appears to be independent of the temperature

Kapitza's researches have a direct bearing on the theory of metallic conduction He has proved that both in a transverse and in a parallel magnetic field the increase in the resistance of the metal conductor due to the field is directly proportional to the first power of the applied field His pioneering experiments on the resistance of metals in very intense fields bring this out clearly Modern theories are based on the assumption that the paths of the free electrons are deflected in their motion by the magnetic field They lead to the conclusion that the effect must follow a square law As this is not true the phenomenon cannot be merely due to the obstruction of the paths of the electrons Kapitza gives a theory which assumes that the change of resistance follows a linear law with the increasing field This effect is masked in weak fields by disturbances existing in the metal which are equivalent to that produced by an inside magnetic field He obtains formulæ which agree with the experimental facts and permit the separation of the ideal resistance and the additive resistance which is produced by internal disturbances

It has been observed by Kamerlingh Onnes and others that close to the absolute zero of temperature there is a residual resistance This resistance is the additive resistance which is independent of the temperature

The other component of the total resistance which Kapitza calls the ideal resistance has a constant value for a given temperature in each metal and is independent of the chemical and physical state of the metal Mercury thallium tin lead and indium which are supra conductors were very carefully examined but no exception to the general law in their change of resistance in magnetic fields was observed The experiments definitely indicate that the phenomenon of supra conductivity consists in the disappearance of the additive resistance The resistance of the conductor is then equal to its ideal resistance It follows that supra conductivity is not a phenomenon confined to a few metals but probably exists in all metals The temperature however has to be reduced sufficiently low to make the additive resistance disappear

University and Educational Intelligence

BRISTOL One or more research studentships in experimental physics are being offered for the session 1929–30 The emoluments will be from £200 to £300 and the studentships may be renewed for a second or a third year Further particulars may be obtained from Prof Tyndall to whom applications should be sent before May 25

A studentship in theoretical physics is also offered for the session 1929 30 of the value of from £200 to £300 and the studentship may be renewed for a second or a third year Further particulars may be obtained from Prof Lennard Jones to whom applications should be sent before May 25

CAMBRIDGE —The Amy Mary Preston Read scholarship of value £150 for research in a scientific subject, has been awarded to H D Ursell scholar of Trinity College B H C Matthews Beit Memorial Fellow 1928 has been elected a fellow of King s College

EDINBURGH —At a graduation ceremonial on Mar 21 the degree of doctor of science was conferred on Gwendoline Hilda Faulkner for a thesis on The Anatomy and the Histology of Bud Formation in the Serpulid *Filograna implexa* on Mr J M Gulland for a thesis on The Morphine and Aporphine Alkaloids and on Mr T A Sprague for a thesis on Taxonomic Studies in *Loranthus* and other Phanerogamic Genera

LONDON —Dr Paul Dienes senior lecturer in mathematics at University College Swansea has been appointed as from Aug 1 to the University readership in mathematics tenable at Birkbeck College Dr Dienes was educated at the Presbyterian College of Debrecen Hungary and the University of Budapest where he obtained his doctorate in 1905 On graduation he was appointed lecturer in mathematics at Budapest In 1908 he was given two years leave of absence to study in Paris and obtained the doctorate of the University

of Paris in 1909 From 1918–19 he acted as adviser to the Commissioner for the re organisation of the University of Budapest, and in 1919 he organised the Faculty of Science in the new Calvinistic University of Debrecen, Hungary His publications include "Leçon sur les singularités des fonctions analytiques" (Gauthier Villars, 1913), "Taylor Series an Introduction to the Theory of Functions of a Complex Variable" (Oxford Univ Press, in the press), and numerous papers in French, Hungarian, and Italian scientific journals

The degree of D Sc in anatomy has been conferred on Mr W B Crow (East London College), for a thesis entitled "Contributions to the Principles of Morphology"

An Academic Diploma in Public Health is to be instituted

Oxford —The fifth Annual Report of the Lewis Evans Collection of Scientific Instruments was presented to Congregation on Mar 19 It contains an interesting note on the original carved panels on either side of the east window of the Old Ashmolean Museum The carving represents marine shells and exotic fruits, having a direct reference to the use of the Museum for illustrating the natural productions of lands oversea, an object, as Mr R T Gunther, the curator, points out, always uppermost in the minds of the Tradescants and of Elias Ashmole The report also records a long list of accessions, and speaks with appreciation of the encouragement derived from the inauguration during the year of a 'Society of Friends of the Old Ashmolean"

The electors to the professorship of engineering science propose to proceed to the election of a professor in the course of the ensuing Trinity Term Applications must reach the Registrar not later than April 27

There will be an election to Beit Memorial junior fellowships in medical research in July next Forms of application and all information can be obtained on request by letter addressed to Sir James K Fowler, 35 Clarges Street, W 1 The latest date for the return of application forms is June 1

Applications for a Ramsay Memorial Fellowship for Chemical Research, the annual value of which is £250, with the possible addition of not more than £50 for expenses, should reach the Secretary of the Ramsay Memorial Fellowships Trust, University College, Gower Street, W C 1, by, at latest, June 5

Applications are invited for scholarships for the promotion of research in sanitary science which have been established by the Grocers Company The annual value of each scholarship is £300, plus an allowance for expenses and the tenure is for a year, with a possible extension for a further year or two years Application forms, returnable before the end of April, may be obtained from the Clerk to the Grocers Company, Grocers' Hall, E C 2

The Board of Regents of the University of the Philippines has established a Baker Memorial Professorship in the College of Agriculture This professorship, which is in memory of Charles Fuller Baker, who was dean of the College of Agriculture from 1917 until his death in July 1927, provides for the services in the College of a man from abroad who shall be in residence and teaching in the College eight months at least, and it is proposed to secure men who are specialists in the different sciences allied to agriculture

Calendar of Patent Records

April 1, 1614 —On April 1, 1614, there was granted to William Ellyott and Mathias Meysey an English patent for the first cementation process for converting iron into steel, and steel was successfully produced by the inventors and by Sir Basil Brooke, to whom the patent was transferred in 1618 A second patent containing extended privileges was granted to Ellyott and Meysey, but a clause in it prohibiting the importation of steel created international complications and the patent was revoked

April 1, 1773 —It is not often that an invention is considered worthy of a public monument within a year or two of its birth But this happened in the case of David Hartley's invention for securing buildings against fire by means of thin iron plates laid under each floor and in the ceilings, which was patented on April 1, 1773 The invention was adopted in a number of buildings and received extraordinary support from the Corporation of the City of London, which not only attended officially at a full scale trial of the invention, but erected an obelisk, which still stands, on Wimbledon Common, and made Hartley a freeman of the City Parliament, too, was not far behind It voted £2500 to enable the inventor to carry on his experiments, and extended the duration of the patent for thirty one years from 1777

April 2, 1712 —The first specification of an invention to be enrolled in the High Court of Chancery pursuant to a definite proviso in the patent grant was enrolled on April 2, 1712, in connexion with John Nasmith's patent, No 387, for "the preparing and fermenting of wash from sugar molasses and grain" The wording of the grant shows that the insertion of the proviso, which later became a regular requirement of the Crown, was the suggestion of Nasmith himself (Cf this Calendar, Feb 29 and Mar 13)

April 3, 1449 —The patent granted by Henry VI to John of Utynam on April 3, 1449, for the exclusive right of making coloured glass, is the earliest known example of an industrial monopoly patent in England or any other country John of Utynam came from Flanders at the King's command to make windows for colleges at Eton and Cambridge, and the grant recites that because the said art had never been used in England, and John intends to instruct divers lieges of the King in its practice, no subject of the King is to use it for a term of twenty years, against the will and consent of John, under a penalty of £200

April 4, 1785 —One of the outstanding inventions of the eighteenth century—the power loom—was patented by the Rev Edmund Cartwright on April 4, 1785 Neither this nor his other patents brought much reward to the inventor, but he received a special parliamentary grant in 1809 in recognition of his services to industry

April 5, 1839 —Josiah Marshall Heath's patent, dated April 5, 1839, for the first practical process for the manufacture of manganese steel, gave rise to one of the hardest fought law suits in the annals of British patent law During the protracted proceedings the case at one time or another came before no fewer than 18 different judges—of whom 7 decided in favour of the patentee and 10 against—as well as the Privy Council and the House of Lords, and the final verdict of the latter was not delivered until 1855, thirteen years after the commencement of the suit and after the death of Heath himself The value of the invention to industry was not in question, and the Privy Council recommended the extension of the grant for seven years, but this decision was rendered nugatory and the case brought to a close by the final judgment of the House of Lords against the inventor

Societies and Academies.

LONDON

Geological Society, Mar 6 —**Mrs M M Ogilvie Gordon** Structure of the Western Dolomites She described briefly the stratigraphical succession of the Permian and Triassic rocks which mainly compose the mountain lands of the Western Dolomites, and showed their character in a number of photographic slides Special attention was given to the outbreaks of volcanic action which took place in the Upper Buchenstein and Wengen periods at the close of the Alpine Middle Trias The leading structural features were described, with the aid of the geological map of the Gröden and Fassa district published by the lecturer in 1927

Institute of Metals, Mar 14 —**W Rosenhain** and **W E Prytherch** An improved form of electric resistance furnace Higher available working temperatures (up to 1400° C), durability, and freedom from oxidation of the carbon resistor are claimed The heating element consists of carbon or graphite pellets, or short rods placed end to end in a refractory sheathing tube which fits easily over them Heating occurs by contact resistance The sheathing tube prevents the access of air sufficiently to avoid any appreciable burning of the carbon —**C Sykes** Alloys of zirconium (2) Measurements of electrical and magnetic properties of copper zirconium, iron zirconium, and nickel zirconium alloys show that zirconium gives no material improvement in the properties of the metals, and in certain cases is detrimental Two further partial series of binary alloys are described – aluminium zirconium and silver zirconium The systems exhibit little solubility in the solid state at room temperatures and intermetallic compounds are formed In the low percentage alloys (10 per cent) the compounds crystallise in the form of long, fine needles, and consequently the structure of the alloys is very coarse —**J Newton Friend** and **W E Thorneycroft** The resistance of zinc to indentation (a preliminary account) A machine is described for determining the rate of indentation of zinc by a steel conical die acting under small gravity loads —**J Newton Friend** The solution of plain and amalgamated zincs in electric batteries For use in electric batteries with dilute sulphuric acid or with saturated ammonium chloride solutions, plain high grade 99 9 per cent zinc cannot satisfactorily replace the amalgamated metal or amalgamated pure zinc —**J Newton Friend** and **W E Thorneycroft** The silver contents of specimens of ancient and mediaeval lead Twenty specimens of ancient, Roman, and mediaeval lead have been analysed Spartan lead votive figurines, c 700–500 B C, contain 0 0568 per cent silver, or 18½ oz silver per ton The pre Roman lead does not appear to have undergone any treatment for desilverisation

CAMBRIDGE

Philosophical Society, Mar 11 —**N F Mott** The quantum theory of electronic scattering in helium Born's calculation of the electron scattering in atomic hydrogen is extended to the case of helium The results agree well with experiments of Dymond and Watson —**H M Cave** Note on the number of high velocity β rays By a simple magnetic field method, it is shown that, for radium B + C, the number of β rays having energies greater than 12,000 $H\rho$ must be less than 1 per 500 disintegrations, and is probably less than 1 per 1000 disintegrations —**J L Hamshere** The mobility distribution and rate of formation of negative ions in air The Rutherford Frank Lattey 'alternating field' method of measuring ionic mobilities in a gas has been modified Negative ions in dry air have a continuous mobility distribution between the limits 2 15, 1 15, with a peak value about 1 8 At pressures below 50 mm (Hg) the current is resolved into ions and free electrons The ratios of the ion and electron currents show that the electron makes in air a mean number of $9\ 4 \times 10^4$ collisions before capture, independent of electron velocity over a range 2 to 7×10^6 cm /sec

DUBLIN

Royal Irish Academy, Feb 25 —**Miss M C Knowles** The lichens of Ireland In the arrangement of the list, Praeger's topographical divisions are used and the classification and nomenclature of the "Monograph of British Lichens" 801 species are recorded, among them 7 new to science and 5 to the lichen flora of the British Isles —**Rev R J Doyle** and **H Ryan** Periodic precipitation in the presence and absence of colloids The equation of Jablczynski giving the relation between the distances of bands formed during periodic precipitation in the presence of colloids, and also the equation of Morse and Pierce, hold approximately for the banded precipitation of calcium hydrogen phosphate in the absence of colloids The presence of the colloid cannot therefore be the main factor in the phenomenon It was also shown by means of indicators in gels that the diffusing reagent is far in advance of a point at which a band begins to form The colour changes of the indicators showed clearly that band formation does not occur in the diffusing wave front as some theories of periodic precipitation appear to assume

PARIS

Academy of Sciences, Feb 18 —**L Lecornu** The Clapeyron cycle in the case of saturated vapours —**H Douvillé** The Western Pyrenees at the commencement of the Eocene and the formation of the chain —**V Grignard** and **Tchéoufaki** The additive properties of the α diacetylenic hydrocarbons Oxidation with weak (1 2 per cent) potassium permanganate solution in acid solution gives a product of hydration and not of oxidation stronger solutions (5 6 per cent) give oxidation products The addition of water (sulphuric acid, mercuric chloride) gives always a β diketone Shaking with oxygen gives partial hydration —**T Nagell** The rings of algebraic integers —**A Khintchine** A generalisation of some classical formulæ —**L Lusternik** and **L Schnirelmann** The existence of three geodesics closed on the whole surface of genus 0 —**Th Anghelutza** A new class of nuclei for a Fredholm equation —**Vladimir Bernstein** The singular points of functions represented by Dirichlet's series —**Jacob** The application of Fourier's generalised integrals to the calculus of probabilities —**N Neronoff** A continuous irrotational movement in two dimensions of an indefinite fluid in the presence of a fixed cylindrical obstacle —**Pierre Dupin** A new method of measuring the velocity of fluids based on the use of valve oscillators A description with illustrations of an apparatus showing the velocity of a fluid by a direct reading on a graduated scale It is based on the modification of the wave length of an oscillating circuit produced either by a variation of capacity or by a variation of the self induction of the circuit under the influence of the velocity of the fluid The condenser readings are a linear function of the velocity —**Benjamin Jekhowsky** The corrections of the ephemerids of the minor planets —**A Véronnet** The origin of the planets and the formation of the world —**Y Rocard** Hydrodynamics and the kinetic theory of gases The wall limiting the fluid absorbs molecules

and sends them out according to a law of distribution of velocities other than that of Maxwell Near the wall of the vessel the gas or liquid is no longer a fluid and the equations of hydrodynamics are not satisfied At distances greater than three or four times the mean free path, the ordinary laws of fluids hold —**Jean J Trillat** The orientation of organic compounds by cylindrical glass surfaces and the superficial orientation of the glass —**Ballay** The cathode yield in the deposition of nickel with high current densities The influence of oxidising agents and of the hydrogen ion concentration —**Pierre Bonnet** The tectonic structure of southern Transcaucasia —**Kadlec-Fleck** The synthesis of cyanamide by combinations of carbon and calcium nitride Calcium nitride reacts with carbon at a red heat, giving cyanamide and calcium carbide Between 800° C and 1100° C the rapidity of the reaction increases with the temperature Above 1000° some calcium cyanide is also produced —**Luigi Umberto de Nardo** A new method of colorimetric estimation of nitrates in soils and waters This method is based on the use of pyrogallolsulphonic acid as reagent —**Aug Chevalier** and **W Russell** The sub family of Erisma **P Mazé** The mean temperature of the leaves of maize exposed to sunlight — **Lucien Daniel** The heredity of the ligneous transformations in the descendants of grafted Jerusalem artichoke and sunflower —**Raymond Poisson** The presence in the south of France of an American Hemipter homopter of the family of the Membracidæ *Ceresa bubalus* and its biology This insect which seriously affects certain cultivated plants was noted in France (Eastern Pyrenees) in 1927 and its possible extension must be watched **F Maignon** and **A Painvin** The influence of the seasons on the respiratory combustions of the dog —**Pierre Marié** The arthropods inhabiting the burrows of the Alpine marmots —**E Aubel** The relation between the production of lactic acid and the growth of yeast —**M Javillier** and **Mlles S Rousseau** and **L Emerique** The chemical composition of the tissues in A avitaminosis phosphorus lipoid extract cholesterol **Mlle A Michaux** The total albumens (seroalbumen or serine and serumglobulin) of the serum of guinea pigs suffering from scurvy The presence of albumen and hæmoglobin in the urine of animals at the end of the disease —**E Wollmann** and **Ach Urbain** The reaction of fixation in grafted tumours of mice **R Douris Ch Mondain** and **Mlle M Plessis** The differentiation of normal and pathological sera The oxidisability of the sera The diluted sera were oxidised by a chromic sulphuric acid mixture under comparable conditions The oxidation coefficient expressed as oxygen absorbed, was least for cancerous sera higher for syphilitic sera, and highest for normal sera The coefficients overlap to an extent which deprives the method of diagnostic value

SYDNEY

Royal Society of New South Wales, Dec 5 —**A R Penfold** and **F R Morrison** The chemistry of the exudation from the wood of *Pentaspodon Motleyi* This tree occurs in New Guinea and is identified as close to *Pentaspodon Motleyi* The crude oil was non volatile in steam and could not be distilled without decomposition at 1 mm It contained 90 95 per cent of a new monocarboxylic acid of molecular formula $C_{24}H_{34}O_4$ The silver and copper salts are the only two derivatives which have so far been prepared —**A R Penfold** The essential oil from a pinnate leaf *Boronia* from Frazer Island, Queensland The oil contains 75 80 per cent safrol limonene, etc It differs in composition from all other pinnate leaf *Boronias* so far described, and on account of the inability of botanists to separate it from *B thujona* it is known tentatively as *B thujona, var A* —**M B. Welch** Examination of defective oregon An investigation was made on portion of an electric crane which broke suddenly in Sydney The wood used was oregon, and mechanical tests showed that the wood was extremely brittle and unable to absorb energy due to sudden shocks Usually wood is far stronger in tension than in compression, but with the timber in question there was little difference in this respect It seems possible that, due to continual reversal of the stresses in the member, the wood had become fatigued —**W R Browne** The probable Tertiary age of certain New South Wales soils It is agreed that accumulation of residual sedentary soils is favoured by low physiographic relief, consequently, when such deposits are found in regions of high relief, they may be regarded as relics from the latest stages of the cycle of erosion immediately preceding Some soils occurring around Sydney, on the Blue Mountains, and elsewhere on the highlands, are believed to have been produced during the Tertiary peneplanation, one indication of this is found in the ironstone gravel or hardpan which is so frequent in these soils and must have been formed under physiographic and climatic conditions very different from those prevailing at the present day —**A R Penfold** The essential oil of a new species of Anemone leaf *Boronia*, rich in ocimene —**W R Browne** On some aspects of differential erosion Examples are given from New South Wales illustrating the effect An explanation is developed of anomalous behaviour of rock masses in regard to erosion, whereby rocks like granite really resistant to mechanical wear, are eroded more quickly than less resistant ones These masses may, during the last phases of the preceding cycle of erosion, have suffered deep and thorough decay, so that on the uplift of the region they succumbed very quickly to river attack —**E Cheel** Further notes on the genus *Boronia*, Some of the specimens dealt with were collected about eighty years ago by Allan Cunningham and other explorers who considered them to be good species, but several of these were reduced to mere forms or varieties by Bentham Seven of the earlier names are worthy of rehabilitation to specific rank, and two are proposed as new species —**W R Browne** and **H P White** Alkalisation and other deuteric phenomena in the saddleback trachybasalt at Port Kembla The changes were produced partly by residual solutions, but mainly by post volcanic solutions, which have given rise to zones of progressive alteration roughly parallel to the intrusive contact, the greatest changes being in the intrusive rock These solutions introduced much soda and potash, the former entering into replacive ablite and the latter partly into sericite, but there is chemical evidence that most of the potash is contained in the albite The term 'alkalisation' is proposed to cover cases of magmatic alteration wherein both alkalis are introduced, or in which either base appears in more than one deuteric mineral —**G L Windred** Notes on some organisms of tomato pulp Counts of micro organisms occurring in commercial tomato pulp revealed the presence of large numbers of various species of moulds, yeasts, and bacteria An organism causing sliminess of the pulp was isolated, it resembled *Bacillus ruminatus* Gottheil, but there are marked differences Gas production in sealed metal cans causing the bursting of the containers is due to (1) production of gas from carbohydrates by the organisms, (2) and the action of the acid produced by them on the metal of the container —**M B Welch** Notes on some Australian timbers of the Monimiaceæ The genera described are *Doryphora, Atherosperma, Daphnandra, Mollinedia,* and *Hedycarya* The vessels show scalariform end per-

forations, and are usually very long The wood fibres have more or less bordered pits, and reach a maximum length of almost 3 0 mm in *Doryphora sassafras* A key is given for the identification of the woods, based on the microscopical characters — C Chilton Note on a fossil shrimp from the Hawkesbury Sandstones.

Educational Broadcasting

ALREADY we have heard much concerning the powerful influence which broadcasting must have upon what we now accept as civilisation Its effect in helping to break down national and geographical barriers, and its consequent destruction of the suspicions, hatreds, meannesses, and intolerances which ignorance breeds among peoples living within narrow circles, cannot yet be fully estimated That effect is a result of a broad and informal educational influence It is an effect which is inevitable just because broadcasting can not be other than an educational influence If that be the case at present, it is clear that, when the possibilities of broadcasting as a formal and deliberately organised means of education are considered, there can be no doubt that an instrument of incalculable value will be shaped for the service of mankind

The British Broadcasting Corporation is to be congratulated upon the steps it has taken towards linking its activities with the educational system of Great Britain From its early days it has striven untiringly towards that end The history of those steps may be briefly described It began with a committee of inquiry into broadcasting and adult education under Sir Henry Hadow Then followed an interim committee to deal with that specific problem Finally, a central council for broadcast adult education was set up under Lord Justice Sankey That council is composed of representatives of the most important national interests, and it is now completing admirable organisation which will use wireless in the great service of adult education Meanwhile, the famous Kent experiment in the use of wireless to broadcast to schools having been successfully completed, the B B C has just set up a central council for school broadcasting under the chairmanship of the Right Hon H A L Fisher, which is composed of similar national interests to the council we have described above This council is proceeding to deal with the specific problem of broadcasting to schools

The building of such excellent machinery cannot, of course, be productive of anything but good If, then, at the very moment when we wholeheartedly welcome it, we also make one or two suggestions for its use, we feel sure that we shall be acquitted of any desire to make querulous and carping criticism at too early a stage The B B C is, however, a very modern part of modern life, and we would be sorry if it missed the special opportunities it has of taking care that its educational

activities follow, and get the best out of, the changes which are taking place in the structure of our civilisation That does not mean that it should wholly ignore tradition or indulge in a crude stamping upon our special—almost sanctified—academic traditions It means the frank recognition of new values which the changes we have mentioned are presenting us

For our present purposes we have in mind the work of adult education rather than the work of our primary and secondary schools, and we direct attention to what we have called new values because, in a paper on the relation of broadcasting to further education read recently to the Association of Technical Institutions, we see a tendency to make the old distinction between what is called cultural and what is called vocational education "I have often wished," said Mr Siepmann, the author of the paper, "that it were possible to introduce into the technical colleges more subjects representative of the cultural *as opposed to* vocational interests" (our italics) Later he suggested that by "correlating cultural and vocational aims, and by the establishment of a broader basis of instruction, and an attempt to give to the life and work of your institutes a social as well as academic significance," a recruitment of disinterested students would take place Finally, he is "inclined to think that the technical subject [for the purpose of a broadcast talk] is less appropriate than the cultural," and suggested that, while the B B C will go carefully and sympathetically into the matter, there is no "immediate possibility of the extensive adaptation of our programmes to your needs"

If Mr Siepmann thinks that those needs include broadcast talks on engineering or chemistry or building, we are sure he does not yet understand the tone and spirit of the modern technical institution If he thinks that the curriculum of the same institution does not include subjects which he himself would regard as "cultural as opposed to vocational," he is very much mistaken His errors are however, common ones and arise out of the words 'technical education' Much misunderstanding might be removed if Lord Eustace Percy's phrase 'education for industry and commerce' were used It is a term which may be neither entirely satisfactory nor descriptive, but it would help to do away with much of the false distinction between cultural and vocational education—the new phrase under which the ancient and and controversies over, and distinctions between, science and art, tends to be revived

If education is to help in the solution of our problems, we must realise that to treat academic matters apart from social and industrial matters is to fail in all of them What are usually known as academic or cultural subjects are only a part of education In themselves they cannot support life as we know it The spiritual values on which we set so great a store are dependent on what are, at first sight, merely material things But the two cannot be separated Education for industry and commerce can be, and is, used to make men and women realise social relationships Through the grouped course methods of technical institutions, students are shown how one subject is akin to others, how it has value not merely in its own utilitarian content, but also in kinship with others which are at first apparently independent and unconnected

The process is producing a culture which is wider and nobler than our older notions, a culture which is neither lonely nor snobbish, a culture which does not stop short at pleasant abstractions, but is forging a link between the many sides of our world and humanising industry no less than making it efficient Those who know technical institutions know that they are places where is taught not only the art of earning a living, but also the sacred art of living itself

We hope, then, that the B B C 's new educational machinery will not hold too fast to all the parts of academic tradition, that it will realise the vital need for education to march with our changing conditions, that it will be thorough in its examination of phrases like 'cultural and vocational and technical subjects', and that it will regard the changes to which we have referred not as tending to a blind and formless industrialism, but as the outward forms of the newer values which science has made available for us

A Criminal Tribe of India

The Land Pirates of India an Account of the Kuravers, a Remarkable Tribe of Hereditary Criminals, their Extraordinary Skill as Thieves, Cattle lifters and Highwaymen, etc, and their Manners and Customs By W J Hatch Pp 272 + 16 plates (London Seeley, Service and Co, Ltd, 1928) 21*s* net

INDIAN ethnology has been a favourite exercising ground for theorists Recent political developments have done much to encourage them along certain lines Starting from above and adopting the view of a dominant social order, they have

tended to neglect the light to be thrown upon cultural history by direct observation of the more primitive races It is to the credit of the late Sir Herbert Risley, the late Mr William Crooke, and Mr Edgar Thurston, to name some of the principal workers only, that they saw the study of India as a whole and each in his own special province linked up the investigation of primitive and advanced on a basis of observed fact regardless of political or social theory The result is to be seen in Mr Crooke's conclusions as to the relations of the Hindu pantheon and local godlings, and in Mr Thurston's treatment of the out caste and criminal and primitive tribes in the *Madras Gazetteer*

It is inevitable that such reflections should arise on reading Mr Hatch's book on the Kuravers, the tribe whose thieving proclivities have endowed them with the name of 'Land Pirates' It is more than seventy years since officers of the Government whose duties were to prevent dacoity and *Thuggee* first made any study of their peculiarities Yet beyond the notes of police manuals and the accounts in the *Madras Gazetteer*, practically no attempt has been made to give any account of them commensurate with their interest, and this notwithstanding the fact that these nomad thieves are scattered all over the Madras Presidency, as well as in the Canarese Nadu and the Bombay Presidency, and in the Madras Presidency alone number just under two hundred and twenty one thousand The number in the Bombay Presidency also is said to be considerable

The Kuravers are systematic thieves by descent, by habit, and by proclivity They work only when they are not able to steal They wander from village to village but may often earn a lucrative living by a species of blackmail, protecting the villagers from the predatory visits of their fellow tribesmen for a payment Yet the Kuraver, unlike other criminal tribes, as a rule will not kill in order to rob Many of them practise palmistry, the term for which in Tamil is said to be the derivation of their name

It is always interesting, but seldom easy, to trace the origin of a tribe or caste in India General Hervey, the great authority in the middle of the last century on Indian crime, says the tribe migrated from the south, but one version of their origin makes them the descendants of Prince Dharmaraja by a fortune teller (*Kuru*), which would point to a northern descent Their language, however, is Dravidian Physically they are not a low type, and do not differ materially from the other castes of Southern India One story adopted by the Kuravers themselves points to their having at one time lived as hunters and having been driven out by pressure of population Mr Hatch is no doubt right in rejecting the view that they were originally servants of the temples of Southern India, who were supplanted by the arrival of a higher grade of priests

The Kuravers are split up into a large number of divisions, normally each hamlet or settlement containing members of one family only From early times they were distinguished as nomad and settled Four main divisions fall into a number of sub divisions, but there are also other classifications, generally based upon occupation, although this is not necessarily the occupation followed to day Such are the salt merchants, those who split bamboo for the making of baskets, snake charmers, and so on All these ostensible occupations disguise the real occupation of the members of the tribe, which is thieving

The Kuravers worship a number of deities These are, of course, especially propitiated to attain success in thieving expeditions The temple of Subramania at Palni is much frequented by pilgrims Another shrine of great sanctity is that at Chidambaram in South Arcot Magic and superstitious practices loom large in their lives Mr Hatch describes a remarkable belief that a man who has been killed by magic may be resuscitated—a dangerous practice, but one which may prove of great utility, as the nerves extracted from the dead man's legs are most efficacious in the practice of further magic against an enemy

Mr Hatch has had a long experience of the people of whom he writes, but although he describes the tribe and its life very fully and informatively in certain respects, a more systematic account would have been valued In the case of marriage, for example, it is desirable to know what, beyond the bride payment, is the basis of arrangement Marriages are sometimes determined even before the birth of the children, and it is said that a man may claim his sister's two eldest daughters in this way Within what degrees are marriages forbidden or prescribed ? It is also desirable that the position of women should be more precisely defined Mr Hatch implies that their prominence and importance in the Kuraver social system is due in part to the fact that their husbands spend so much time in prison, in part to their utility and their skill in the less important branches of the tribal profession More information upon this and related matters would have been welcome and would have increased the value of this study of a remarkable people

Alchemical Manuscripts.

(3) *Union Académique Internationale Catalogue des manuscrits alchimiques grecs* Publié sous la direction de J Bidez, F Cumont, A Delatte, O Lagercrantz et J Ruska Tome 6 *Michael Psellus, Épître sur la Chrysopée , Opuscules et extraits sur l'alchimie, la météorologie et la démonologie*, publiés par Joseph Bidez, en Appendice, *Proclus, Sur l'art hiératique*, *Psellus, Choix de dissertations inédites* Pp xiv + 246 (Bruxelles Maurice Lamertin, 1928) 15 Belgas

THE history of alchemy has a twofold claim on our attention In the first place, it still has its adherents, who are found not merely in the Orient but also in America, Germany, France, and England itself It was recently related that the philosopher's stone had been prepared at Los Angeles by a woman alchemist, who thus takes rank with Mary the Copt and Cleopatra, while M Jollivet Castelot from time to time issues reports of his successful transmutations That this art should flourish even in the twentieth century is a striking witness to human credulity, and as such may engage the notice of psychologists

Secondly, alchemy is the direct ancestor of chemistry, and in view of the modern trend in the philosophy of science, the importance of a study of origins need not be emphasised here Although there are dissentients, it is commonly believed that chemistry arose in the early years of the Christian era, as a result of the fusion of Egyptian metallurgical and other arts with the mystical philosophies of the Neo Platonists and Gnostics Unluckily, the Neo Platonists regarded matter as the principle of unreality or evil, from which the disciple should attempt to detach himself, while the Gnostics cared little for the phenomena of the sensible world, being much more anxious to attain to a knowledge of the invisible cosmos It is significant for the later history of the science that one of the earliest chemical writers, Zosimos the Panopolitan, was a Gnostic, while the Neo-Platonic conceptions of sympathetic action, action at a distance, the distinction between occult and manifest properties, the influence of the stars, and the mystical powers of numbers, all permeate chemistry from its beginnings at the time of Plotinus until the close of the seventeenth century It would, indeed, scarcely be going too far to say that some of these ideas are with us still nitrogen is manifestly inert but occultly active, and the structure of the atom is ultimately a matter of the relations between numbers, as Prof Dingle has observed

To get a clear picture of the development of chemical thought throughout the ages, a great deal of work remains to be done Even the comparatively recent eighteenth century has been insufficiently studied, and the farther we go back the more hazy does our knowledge become The first step to rectify this unsatisfactory state of affairs is obviously an investigation and classification of the material at our disposal The ancient literature of alchemy was incredibly large, and the number of manuscripts which have survived is by no means insignificant The careful cataloguing of these manuscripts has been undertaken by competent scholars under the patronage of the Union Académique Internationale, and the three volumes now under review represent a valuable continuation of the programme of work

(1) The fifth volume of the "Catalogue des manuscrits alchimiques grecs" deals with the manuscripts of Spain, described by C O Zuretti, and those of Athens, described by A Severyns Certain of the Spanish manuscripts furnish useful data for the study of the relations between the principal Greek alchemical works, while others enrich our knowledge of the "Koeranides" The Athenian manuscripts are but five in number, and four of these date only from the eighteenth or nineteenth centuries, the other being of the fourteenth The modern ones are of value as probably representing more ancient works which have to day disappeared or lie hidden in obscure libraries

(2) Of more general interest is the first volume of Mrs Singer's great catalogue of Latin and vernacular alchemical manuscripts in Great Britain and Ireland, dating from before the sixteenth century Mrs Singer's enormous collection of bibliographical data is of course very well known to all historians of science, few of whom are not indebted to her

for information always promptly and generously given. It is therefore with a gratitude partaking of a hope for future favours that we congratulate Mrs. Singer on the appearance of her catalogue and the British Academy on its liberality in bearing the cost of printing it.

In an excellent little introduction, Mrs. Singer explains the direct Greek influence on Latin alchemy. "The iconoclastic disputes in the Byzantine Empire led to the dispersal of artificers, who carried their workshop recipes with them westward. In the work of the eleventh century chronicler, Adam of Bremen, we read of a converted Jew named Paul who, after having visited Byzantium, came to Bremen bringing with him the art of transmuting copper into gold." Several alchemical or rather technological manuscripts of evident Greek ancestry are described in the catalogue, and practical chemistry of a primitive nature was clearly practised in Europe before the great influx of chemical knowledge from Islam in the twelfth and thirteenth centuries. This influx is manifested by the appearance of Arabic names, technical terms, and forms of expression, and in several cases we are in possession of the original Arabic texts of Latin alchemical works. Mrs. Singer's catalogue will doubtless help us to find other such cases, for several of her titles are strongly reminiscent of Arabic alchemical books. We notice, for example, a treatise by 'Mirer,' whom we should guess to be Mahararis, a Muslim alchemist about whom little is known but of whom some writings are extant; and a 'filius Hahmil,' who is undoubtedly Ibn Amyal, as the *incipit* of the manuscript agrees with the opening sentence of an Arabic work by him. These are but foretastes. Mrs. Singer's catalogue is as full of good things as a Christmas pudding and will require even more digestion. We may perhaps direct special attention to the large number of manuscripts in English.

(3) Volume VI. of the Greek catalogue is devoted to a study of Michael Psellus's "Letter on Gold making," by Joseph Bidez, with appendices on certain inedited dissertations of the same writer and a tract of Proclus "On the hieratic art." Psellus, who was professor at the Academy at Constantinople about the middle of the eleventh century, expressed very enlightened views upon the study of Nature. Contemporary indifference to natural phenomena aroused his indignation as only too likely to perpetuate or re-awaken ancient superstitions. He believed in the possibility of the transmutation of the metals, but denied that a knowledge of alchemy was a secret confined to the initiated. The operation of the alchemist, he considered, finds its explanation in the Aristotelian theory of the four elements, from which everything comes by combination and into which everything is resolved by dissolution. Nothing, he says, is produced without cause; belief in prodigies is merely a result of our lack of comprehension of the causes of phenomena. It is not without interest, in view of the fact that at this time Arabic works were being translated into Greek, that Avicenna had expressed an almost identical opinion in 1022, when he wrote (concerning a 'natural wonder'), "These things appear strange only on account of their infrequent occurrence," the wonder vanishing when the causes are known.

One thing emerges very distinctly from the study of ancient scientific treatises. It is that scientific genius and scientific method are not entirely the monopoly of post-Galilean days; but that the great advance which science has made during the last three hundred years is due in no small degree to better co-ordination and transmission of ideas by a much greater number of workers, rather than to any sudden efflorescence of scientific ability.

E. J. Holmyard.

A Hunter-Naturalist's Memories.

Retrospect: Reminiscences and Impressions of a Hunter-Naturalist in Three Continents, 1851–1928. By Abel Chapman. Pp. xix + 353 + 56 plates. (London and Edinburgh: Gurney and Jackson, 1928.) 25s. net.

Mr. ABEL CHAPMAN'S "Retrospect" is a fascinating volume, richly illustrated from his own drawings and with coloured plates of singular beauty from those of the late Mr. Joseph Crawhall. While most of the chapters will appeal chiefly to sportsmen, the author, as a trained and vigilant observer of animal behaviour in many lands, provides just the kind of observation usefully to complement work in the laboratory and the museum. He is puzzled by the enigma how animal and vegetable life can persist in waterless, rainless, dewless African deserts.

"In the Sudan we have two closely related forms of the hartebeest group, namely, the Tiang (*Damalescus tiang*) and the Korrigum (*D. korrigum*), animals so nearly alike that a casual observer would scarce differentiate between them; yet, as regards thirst, as wide apart as the poles in their habits. The tiang is a thoroughly bibulous beast. It inhabits the Steppe regions bordering on the White Nile, and is specially careful to resort twice a day to that river . . . and enjoy two long drinks; . . . the korrigum elects to reside permanently in

the waterless deserts of Kordofan, hundreds of miles from the Nile, and where never a drop of pure water can moisten his torrid throat and tongue year in and year out It is a contrast that passes understanding" (pp 144 5)

Finding it equally perplexing to comprehend how the plants on which the korrigum feeds can exist without water, Mr Chapman put the case before the late Sir Isaac Bayley Balfour, and gives the following extract from his reply

"Plants growing in waterless deserts are variously attuned to their environment Some may store water to tide them over long periods of drought Others, such as the mimosas which you indicate, are able to hold such water as they may obtain in the wood tissues which they form, and also obtain a certain amount from the atmosphere The roots of these plants spread for long distances, and their rootlets attach themselves very firmly to the particles of sand in the soil There may be no *free water* in the soil, and yet an adequate amount of what we call 'hygroscopic water' in the particles, and from these particles the root hairs of plants may get their supplies"

Mr Chapman differs emphatically with those who entertain what he describes as "the Doctrine of Colour Protection," regarding it as "based upon the supposition or superstition that the Almighty had so camouflaged His creatures as to render the harmless invisible to their enemies, while the enemies themselves were equally aided in their predatory avocation by an obliterative coloration" (p 118) This is scarcely a fair summary of the conclusion at which many observers have arrived, which, indeed, is confirmed by Mr Chapman as an experienced field naturalist, for he admits that many animals assimilate so closely in colour to their environment as to be "virtually invisible to the human eye" (p 122), but as they are easily detected when they move, he objects to their colouring being pronounced protective

No one can have given much attention to birds without recognising in how many species colour serves the male for display and the female for concealment during incubation This is almost universal in the duck tribe, although the Sheldrake, *Tadorna cornuta*, presents a significant exception, the female being well nigh as brilliantly garbed as her mate, wherefore hereditary prudence causes her to incubate subterraneously in rabbit burrows

Among fishes also, the remarkable result of Dr Francis Ward's observation from his subaqueous chamber was to reveal how faithfully the glittering sides of certain fishes reflect surrounding water weeds, stones, etc, with protective effect Mr Chapman's long experience in various climes enables him to show that in very many wild animals their colouring is the reverse of protective, but it is unphilosophic to describe as "poetic theorists" (p 133) those who recognise a protective result from the colouring of certain other animals

It is a feature of these reminiscences that while in one chapter the author expresses vigorous dissent from the opinions formed by other naturalists, in another chapter he approves of action founded on those opinions Thus, while he denounces the enactment of a close time for water fowl in Britain as one of the "long drawn bungles of those in high places at the instance of hysterical protectionists" (p 42), he applauds enthusiastically similar legislation which has saved the Spanish ibex, *Capra hispanica*, from extermination (p 99)

A discussion on the maximum speed of flight attained by different kinds of bird is an interesting essay contribution on a difficult problem which Mr Chapman does not claim to have solved, but suggests that, whereas Flight Lieut Webster in the international aeroplane trials at the Lido in September 1927 registered a speed of 289 miles an hour, the speed of bird flight has hitherto been greatly under estimated (Chap xiv)

Since this notice was written, the reviewer has learnt with sincere regret that the author is no more—regret that must be shared by all who esteemed Mr Chapman as an experienced naturalist, a skilful draughtsman, and an entertaining writer

HERBERT MAXWELL

Photographic Star Fields

Isaac Roberts' Atlas of 52 Regions a Guide to Herschel's Fields (avec texte anglais et texte français) Edition commemorating Isaac Roberts' Centenary (1829–1904) By Mrs Isaac Roberts (*née* Dorothea Klumpke) Pp 44+61 plates (London Wheldon and Wesley, Ltd, n d) 42s net

IN the *Philosophical Transactions*, 1811, Herschel gave a list of fifty-two regions in the sky which he described as showing "extensive diffuse nebulosity" Little attention would appear to have been given to the matter at the time, and it was not until 1862, when Auwers reprinted the list, that we find further mention of the fields in question Thirty years later, Barnard reprinted the list in *Knowledge*, but again no observations are recorded

It was to determine the presence and extent of the nebulosity observed by Herschel that, in 1903,

Isaac Roberts undertook a systematic examination of the fifty-two fields Roberts photographed each field simultaneously with his 20 inch reflector and with a 5 inch Cooke lens The result of this survey was given in a paper which appeared in the *Monthly Notices*, *R A S*, vol 63 In this, Isaac Roberts reported that in four of the regions only had his photographs confirmed Herschel's observations In the other forty eight regions no trace of nebulosity was shown on his plates In recording this he was reporting the result of a survey taken on a definitely determined plan laid down beforehand The exposure time given to both series of photographs was ninety minutes, this being considered sufficient to show any nebulosity likely to have been seen by Herschel It was pointed out at the time that both Max Wolf and Barnard had photographed nebulosities in some of these forty eight areas There the matter rested for a while, until, in 1926-27, Father Hagen published the results of his visual survey, in which he confirmed Herschel's observations

As a tribute to the memory of her husband, Mrs Isaac Roberts now publishes an atlas of the fifty two regions, consisting of sixty plates, reproduced from the original negatives taken by him in the course of his survey The atlas is remarkable for the care which has evidently been taken to ensure a faithful copy of the original plates As photomechanical reproductions of astronomical photographs they are amongst the finest we have seen The atlas, as a whole, is very tastefully got up, and it is an easy matter to make identifications on the plates, full particulars being given on each sheet The plates are reproductions in ' negative,' the stars appearing as dots on a white ground, undoubtedly the best way of reproduction To those interested, this atlas should prove to be one of the greatest value The plates have been reproduced on an enlarged scale of 10 mm =6 3′ for reflector plates and 10 mm =32′ in the case of the 5 inch lens photographs

The text which accompanies the atlas contains a short account of Herschel's observations of the fields, followed by Isaac Roberts' report on the result of his photographic survey A very full and complete description of the charts, accompanied by tables, is also given There is also a chart showing the distribution of the fifty two areas, which are somewhat scattered over the northern hemisphere and extend to 100° N P D In a preface, Father Hagen, Director of the Vatican Observatory, gives a historical account of the observations of these regions of the sky hitherto made

In publishing this series of plates, Mrs Isaac Roberts could not have chosen a more fitting manner of paying tribute to the memory of one who was a pioneer in astronomical photography, and whose work in this direction gained for him the well merited reward of the gold medal of the Royal Astronomical Society The plates now reproduced are further evidence of the skill and devotion with which he applied himself to his task

No doubt many will be glad to know that copies of the atlas may be purchased

Our Bookshelf

Ice Cream a Textbook for Student and Manufacturer By Prof G D Turnbow and L A Raffetto Pp ix+407 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1928) 20s net

The making of ice cream has become an important branch of the dairy industry in the United States, and the above volume has been written to serve as a text book for students—instruction in ice cream manufacture is now given in thirty of the State colleges in America—and a reference book for those engaged in the trade

The material in the book is well arranged First a historical introduction, then, after a discussion of the food value of ice cream, three chapters are given to recipes used in making the many different kinds of ice cream which are mentioned, some of them of an elaborate nature The use of fresh fruit and fruit juices plays an important part in these recipes In another chapter the basic materials of ice cream—milk, cream, butter, sugar, gelatine, and eggs—are dealt with, and a number of formulæ by which the proportions of the ingredients for any mixture may be calculated are given Mixing is followed by pasteurisation and after this operation the mixture is homogenised, to break up the fat globules and increase the dispersion of the fat, then comes the freezing of the mixture Complicated machinery is required for the last two operations, and a good account of it is furnished An important chapter is the one dealing with the various engineering questions connected with the running of a modern ice cream plant As dairy products are the main raw material, methods for their analysis are given, as are also methods of bacterial analysis

Although the manufacture of ice cream in Great Britain in no way approximates to the industry in the United States, there are no doubt many to whom this book will appeal, and to them it can be strongly recommended Perhaps in time—and a start has already been made—ice cream will become as popular in England as in America, it is clear that an increase in consumption will be to the benefit of the dairy industry Already there is a demand on a small scale for instruction in ice-cream making, and two at least of our dairy institutes have taken up the subject

Dielectric Phenomena 2 *Electrical Discharges in Liquids* By S Whitehead Edited with a Preface by E B Wedmore (Published for the British Electrical and Allied Industries Research Association, being Reference L/T 30) Pp 137 (London Ernest Benn, Ltd, 1928) 12s 6d net

IN the first volume of this treatise, Mr Whitehead discussed electrical discharges in gases So long ago as 1905, A Russell pointed out (*Proc Phys Soc*, vol 20, p 49) that the maximum stress at which a spark ensued between spherical electrodes immersed in a gas was constant within certain limits In 1910 the same physicist pointed out (*idem*, vol 23, p 86) that an algebraical expression of the form $A + B/\sqrt{a}$, where A and B are constants and a is the radius of either of two cylindrical electrodes, could be used to predict the stress at which ionisation begins in air

Since then, an immense amount of research to discover new laws and to show how the results could be applied to testing commercial materials has been done When the electrodes are in a liquid and the voltage is raised sufficiently, an unstable rise in the small conduction current takes place at a definite voltage This may discharge the electrodes or may result in the formation of an arc This phenomenon the author terms 'spark over in liquids' Previous to its occurrence, transient flashes sometimes pass between the electrodes, or streamers may spread out into the gap In rare cases a glow may be observed previous to the sparkover, somewhat similar to the corona we see in air In most cases the electric strength of a liquid depends on the impurities in the liquid, and hence a distinction has to be made between the electric strength of the pure liquid and the liquid in the commercial state The author states that theories put forward to explain the variation in the electric strength of liquids generally discuss merely the behaviour of the impurities It appears that to get formulæ for the electric strength in these cases both the effective and the maximum potential difference have to be taken into account

Organic Syntheses an Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals Roger Adams, Editor in Chief Vol 8 Pp vii + 141 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1928) 10s net

THE editors direct attention to two distinct processes for making both β-chloropropionic acid (from acrolein or trimethylene chlorohydrin) and trimethylacetic acid (from *tert* butyl chloride or pinacolone) One of the most interesting of the preparations included in the volume is that of *l* arabinose from mesquite gum This material, which is collected by the natives in the south-western United States and northern Mexico, is stated to furnish from 36 to 46 per cent of its weight of crude *l* arabinose, and a yield of 25 4 per cent of the purified sugar is mentioned in the preparation described The raw material is said to be abundant, the process is simple, and the yields are comparatively high A detailed description of Prof Roger Adams's apparatus for the catalytic hydrogenation of organic compounds is another feature of this volume which merits particular mention, for a working account of a really dependable apparatus of this type has long been needed Prof Adams's hydrogenator is simple in construction, and the reviewer gladly avails himself of this opportunity of testifying to its effective working in actual laboratory practice J R

Fluorescenz und Phosphorescenz im Lichte der neueren Atomtheorie Von Peter Pringsheim (Struktur der Materie in Einzeldarstellungen, herausgegeben von M Born und J Franck, Band 6) Dritte Auflage Pp vii + 357 (Berlin Julius Springer, 1928) 24 gold marks

THE first edition of Prof Pringsheim's book appeared in 1921, and it consisted of just over two hundred pages The preface to the third edition is dated Christmas 1927, and this edition consists of more than three hundred and fifty pages Yet it is clear that the author must have used considerable restraint in order to keep the new edition within these bounds, when we remember the large amount of important work which has been published during the interval between 1921 and 1927 For example, we have the important work of Cario and his collaborators on the phenomena produced by collisions of the second kind, and researches, such as those of Wood and Ellett, on the polarisation of resonance radiation

Prof Pringsheim carefully describes all these new advances, and his book is a very useful guide to the whole subject of fluorescence and phosphorescence The subject is a very large one, which is continually growing at a rapid rate, and it is interesting to remember that the recent work on the newly discovered Raman effect must already have provided sufficient material to encourage Prof Pringsheim to look forward to the appearance of a fourth edition of his book

Manuel de photographie Par H Vial (Bibliothèque professionnelle) Pp viii + 276 (Paris J B Baillière et fils, 1928) 16 francs

THE pages are not very large, nor are they exceedingly numerous, but M Vial has justified the title of 'Manual of Photography" by giving the essence of each subject described, and avoiding such matter as belongs more properly to trade lists and circulars The treatment is quite modern, including desensitising, sensitometry, enlarging, bromoil, ozobrome, photography of coloured objects, photography in colours (autochrome), and stereoscopic work The subject is divided into four parts (1) General and introductory, including elementary optics, objectives, perspective, and apparatus, (2) the negative, (3) the print, and (4) sundry matters mentioned above, and the use of artificial light The illustrations are all helpful and nearly all are original, and the practical directions are sufficient in the more important sections

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Cameroon Gorilla.

IN NATURE of Dec. 24, 1927, Sir Arthur Keith discussed a collection of gorilla skulls which I made in the Mamfe district of the Cameroon. German authorities had long separated this western race from the better known Congo gorilla and had given the Cameroon gorilla the title of *Gorilla gorilla diehli*. Yet no skin of this new species has yet been described, and so great an authority as the director of the Berlin Zoological Museum has even doubted if the species still exists.

Two skins have recently come into my possession from the heart of the Mamfe area, one of which is a mature female, while the other is alleged to be her offspring and is a female of two or three years. In each case the skull was tied to the skin.

The coat of the infant is entirely black except for a patch of brown hair between the ears stretching five inches back from the forehead. There are however, a few sparse white hairs on the back, but not enough to render it in any sense grey. It differs from the chimpanzee of the same age in this neighbourhood in that the hair is shorter and coarser. The older female, which is probably the mother, has a coat which is quite black on the flanks and belly, but quite grey on the back except for a patch of brown six inches long above the forehead.

The hirsute appearance is, therefore, in no respect different from the gorilla of the Ubangie district of the Congo, several fresh specimens of which I was privileged to see last year in Major Powell Cotton's magnificent collection. Nor is there any single feature of the skull which is peculiar to this new species.

It is, therefore, open to question whether it is proper to erect a new species or even subspecies on such slender grounds, since such differences as can be shown to exist may well be racial.

The really striking differences between the Cameroon gorilla and his fellow at the eastern extremity of the gorilla belt are those of habit and behaviour. For whereas Carl Akeley and others have described the eastern gorilla as timid and retiring, the Mamfe gorilla is excessively ferocious and neither timid nor shy. Alone among wild animals with which I am acquainted, the adult male gorilla will *always* attack man on sight. This profound alteration in his behaviour as he approaches the western limits of his range might perhaps justify the creation of a new subspecies which could not be justified on anatomical grounds alone.

Akeley's gorilla differed in another important respect from his western prototype, in that he always slept with his female belongings in trees. So far as I am aware, and I have slept among them several times, and as lately as last week, this is never the case with the Cameroon gorilla, among whom the great male will invariably make his bed on the ground at the base of the tree in full view of his females and offspring in their tree beds.

This observation of mine has been held to be original and scarcely authentic, but on reference to the literature on the subject I find that H. von Koppenfels more than fifty years ago made the same observation in reference to gorilla inhabiting the country that lies between the mouth of the Muni River and that of the Congo.

The point I am anxious to emphasise is this: that if wide differences in habits and behaviour can give grounds for the creation of a separate species, then the Cameroon gorilla may fairly claim that distinction. If, however, a new species must show some definite and constant physical variation either in the bones or the hirsute appearance, it is impossible to separate the most easterly gorilla, that from Kivu, from those I have studied in the extreme west in the Cameroon and Nigeria. Such differences as exist are racial and not specific.

Line Absorption Spectra in Solids at Low Temperatures in the Visible and Ultra-violet Regions of the Spectrum.

FROM extrapolation of X-ray data, it is known that the electrons in the N_1 (and N_2) shell of the ions of the rare earths possess *less* energy than those in the O shells. Expressed in terms of the Bohr-Stoner scheme, the electrons in the 4_4 shell are held less tightly than those of the 5_1 or 5_2 etc. shells. According to that scheme the electrons are arranged in the following manner:

Atomic Number of the Neutral Atom	Symbol of Ion	$1_1 \longleftrightarrow 4_3$	4_4	5_1	5_2
57	La^{+++}	closed shells	0	2	6
58	Ce^{+++}		1	2	6
59	Pr^{+++}		2	2	6
71	Lu^{+++}	,,	14	2	6

The proof that the 4_4 shell is gradually filled in this way was completely established by Hund (*Zeit. fur Physik*, **33**, p. 855; 1926). By assuming the above arrangement and the presence of *normal* multiplet coupling between the orbital and spin moments of the electrons, he calculated the character of the most stable energy level for each ion and its corresponding magnetic moment just as if the ion were in the gaseous state. His results were in beautiful accord with the magnetic data on the solids and on their solutions—with but two exceptions.

Similar calculations for the ions of the iron group failed of agreement as might have been expected, since chromic ion, for example, in solution is the molecular ion $Cr(H_2O)_6^{+++}$ due to the water of *co-ordination* and not the atomic ion Cr^{+++} (*Jour. Amer. Chem. Soc.*, **49**, p. 2456; 1927).

Such extraordinary immunity from external coupling as is exhibited by the ions of the rare earths in their magnetic behaviour suggested that their absorption spectra might resemble the line spectra of ions in the gaseous state. The basic electronic level in each case would be, then, the one confirmed by Hund from its magnetic moment.

X-ray data lead to the conclusion that the energy necessary to remove a 4_4 electron completely from its ion is probably within the range of a quartz spectrograph. Indeed, most of the salts are coloured, so that the energies required for electronic activation may be measured through glass. We used a large quartz spectrograph from Hilger and a three prism 'Uviol' glass spectrograph from Steinheil.

Of previous investigations which concern us here, those of Becquerel alone in 1906, in collaboration with Kamerlingh Onnes in 1908, and finally with Kamerlingh Onnes and de Haas in 1925, are the most important. (See the remarkable summary by J. Becquerel in "Gedenkboek aan H. Kamerlingh Onnes," 1922, p. 288.) They studied the absorption spectra of minerals principally, which contained mixtures of rare earth salts, and found that upon lowering the temperature the narrow bands appearing at room temperature

became much narrower, and in some instances attained a sharpness comparable with the line spectra of gases However, they made no recorded attempt to identify their spectra or to evaluate them Their measurements were limited on the short wave length side of the spectrum by the glass (Dewar tubes) which enclosed their crystals

We have begun a systematic study of the absorption spectra of the individual rare earths from room temperature to that of liquid hydrogen, both in the visible and in the ultra violet At present we wish to report the general features of the spectra already obtained, those of gadolinium, samarium, and erbium

Gadolinium —The uniaxial crystal of $GdCl_3\ 6H_2O$ was made from $Gd_2(SO_4)_3\ 8H_2O$ of atomic weight purity prepared under the direction of Prof B S Hopkins of the University of Illinois, to whom we are extremely grateful The spectra were practically identical with that obtained from a crystal from another source The spectrum consisted of about sixty lines similar in sharpness even at room temperature to the emission lines of iron which were used for comparison At room temperature the entire spectrum was in the ultra violet extending to about 2350 A Upon lowering the temperature new faint lines appeared in the visible, and most of the old lines shifted slightly toward the red There was but little change in the spectrum between the temperature of liquid air and that of liquid hydrogen

The substitution of bromide for chloride did not affect the general appearance of the spectrum, but it separated the components of the multiplets a little, displacing some components toward the short and some toward the long wave lengths

From the magnetic moment of gadolinium ion we know that the level lowest in energy is an ^8S term, and by the Hund theory the other basic levels belong to systems of lower and even multiplicity Groups of lines allow themselves easily to be arranged as multiplets in energy diagrams Many of the closely spaced lines appear to have originated by the splitting up of a 'normal' energy level because of the influence of the electrostatic fields of the neighbours of the gadolinium ions, principally by the water molecules We are led to this conclusion by the small change induced by the bromide ion The fact that it displaces the lines in particular groups both toward the short and toward the long wave length regions practically decides that the Stark levels are shifted above and below the 'original undisplaced' energy level

Samarium —$SmCl_3\ 6H_2O$ was prepared from a salt of samarium of unusual purity kindly furnished us by the late Prof C James, of New Hampshire College At room temperature its spectrum consisted of diffuse lines and bands mostly in the region between 3000 A and 5000 A Upon lowering the temperature the lines sharpened and the bands became narrower At the temperature of liquid hydrogen the lines were exceedingly fine, and the uneven intensity of the few remaining bands suggested a complete resolution into lines if the temperature were further reduced At the low temperatures some lines disappeared and new lines, all extremely sharp, made their appearance The appearance of a new spectrum and its increasing prominence, at the lower temperatures, confirmed the expectations derived from magnetic measurements about to be published by one of us They show that samarium ion in the solid state is a mixture of electronic isomers A considerable proportion of the samarium ion (the ratio varying with the temperature) is present in each of two distinct electronic levels differing very little in energy

The spectrum which disappears as the temperature is lowered is due to the thermally excited state, and the new sharp lines which become more intense as the temperature is reduced reveal the presence of the ion that is more stable at the lowest temperatures

Erbium —$ErCl_3\ 6H_2O$ was recrystallised several times from an erbium salt marked pure by the Welsbach Company Its spectrum at room temperature consisted of very diffuse bands, but at the temperature of liquid air, and especially at that of liquid hydrogen, the bands became resolved into lines of extraordinary sharpness These lines clustered in groups, and the latter were separated by rather large intervals The structure of the groups did not suggest band spectra of gaseous molecules, but rather the multiplets of gaseous atoms under the influence of external fields Very few lines were found below 3000 A

We are extending this work to include the other rare earths and are studying especially the influence of other negative ions and of water of crystallisation on the various spectra This work promises quantitative information concerning such influences of far greater sensitivity and accuracy than can possibly be obtained by the use of the double X ray spectrometer with which many similar investigations are being undertaken

Knock Ratings of Pure Hydrocarbons

Messrs Birch and Stansfield have been good enough to send us a copy of their letter in reply to our communication which appeared in Nature of Feb 23 Our remarks on the knock rating of pseudo cumene are taken from the Aeronautical Research Committee Report and Memorandum No 1013 (1925), in which it is stated that the addition of 5 per cent by volume of this hydrocarbon to a common No 1 petrol lowers the H U C R of the latter to the extent of 0 4 per cent, whereas the addition of the same amount of benzene raises the H U C R by 1 0 per cent

With regard to the figures quoted by Mr Birch and Mr Stansfield for trimethyl ethylene and diamylene which do not agree with our own, it will be observed that our figures refer to concentrations by volume, whereas theirs refer to concentrations by weight Therefore, the two sets of figures do not allow of strict comparison, because relations between concentration and anti knock value are often not linear and because of the comparatively large difference in the specific gravities of the two hydrocarbons concerned

The observation that an acid refined unsaturated spirit has a lower anti knock value than the original is readily explained by the fact that quantitative conversion of olefines to polymers is never attained in ordinary refining practice Especially is this the case with the butylenes, amylenes, and hexenes, the hydrocarbons in question, in fact these substances are largely removed by the acid in the form of sulphuric esters Many references have been made of late in the American scientific press to the relative merits of the various methods of anti knock engine testing commonly used, and it has often been observed that exact correlation of the results obtained by different methods is frequently difficult to obtain (Edgar, *J Soc Aut Eng*, **22**, 1, 41, 1928 MacCoull, *Oil and Gas J*, May 10, 1928, p 208) Edgar has pointed out that the apparent discrepancies are probably due to the different fuel air ratios employed It will be apparent that the addition of 20 per cent of such a volatile substance as trimethyl ethylene (B P

38 42° C) will raise the volatility of any spirit in which it is dissolved to a quite appreciable extent, and, because of this, the strength of the explosive mixture reaching the engine cylinder will be considerably altered unless precautions are taken to prevent this or unless the air fuel ratio is standardised in some way

It is highly probable that the difference between our figures for trimethyl ethylene and diamylene and those quoted by Mr Birch and Mr Stansfield is due to such an effect Suffice it to say that in our determinations with the Delco testing unit fitted with the Midgley and Boyd bouncing pin the technique adopted was the same as that used by the Anglo American Oil Co and its associated American interests, and embodied the important recommendations on mixture strength recently made by Campbell, Lovell, and Boyd (*J I E C* **20**, 1045, 1928) The samples of trimethylene and diamylene we used for the engine tests possessed the following properties, which show good agreement with those recorded in the literature

Diamylene	B P 150 156° C
	$D\frac{20°}{4°}$ 8112
Trimethyl ethylene	B P 38 3–38 5° C
	$D\frac{15°}{4°}$ 6669
	$N\frac{15°}{D}$ 1 3910

We agree with the necessity of ensuring that all hydrocarbons are free from peroxides before conducting engine tests owing to their extreme action in promoting detonation (Callendar, *Engineering*, pp 147, 182, 210 1927, Mardles, *J C S*, p 872, April 1928)

We are very interested in the observations of Mr Birch and Mr Stansfield on the auto oxidation of cyclohexene We have observed that cyclohexene possesses a greater affinity for gaseous oxygen than the straight chain olefines (cf Stephens, *J A C S*, **50**, 568, 1928), nevertheless pentene 2 and trimethyl ethylene as well as cyclohexene both decolorise indigo solution and liberate iodine from aqueous hydriodic acid and feebly acidified potassium iodide after exposure to ordinary light and air for a few days Refluxing the hydrocarbons over sodium for some hours destroyed this action, but products of auto oxidation were again detected after a short exposure to ultra violet light Oxidation products such as peroxides and aldehydes have been detected in a cracked spirit long before any formation of gum or any discoloration has been apparent

We have also observed that the two olefines di isobutylene and diamylene react with gaseous oxygen under the action of light much more slowly than do the simple olefines such as the pentenes, while pseudo cumene and m xylene, aromatic hydrocarbons which have not the anti knock properties of toluene, suffer auto oxidation very quickly It therefore appears that in the olefine series, and perhaps in the aromatic series also, ease of oxidation is intimately connected with anti knock action, and in this connexion the phenomenon of auto oxidation is especially interesting, having in mind the results of experiments recorded by Callendar (loc cit) This investigator has shown that peroxides and aldehydes are products of incipient oxidation during the compression stroke of an internal combustion engine, and that the extent of such oxidation is an important factor in the knock rating of any fuel Messrs Birch and Stansfield's views about the compactness of the molecule among isomerides on knock rating are clearly complicated by their remarks on the behaviour of certain members of the aromatic series We feel that insufficient work on this subject has yet been published upon which to base such a generalisation which will apply to hydrocarbons of all types

The Boundary of the Solar Chromosphere

IN connexion with the theoretical side of the question discussed by Mr R W Gurney (NATURE, Feb 16, p 240) and further by Prof F J M Stratton and Mr C R Davidson (NATURE, Mar 2, p 318) the following points may be of interest

In a paper shortly to appear (*Monthly Notices, Roy Astr Soc*, March) I have tried to interpret the recent published measurements of the hydrogen chromosphere At present it is only possible to give orders of magnitude However, putting together the observations of Davidson and Stratton (*Mem Roy Astr Soc*, **64**, 105, 1927) and Davidson, Minnaert, Ornstein, and Stratton (*Monthly Notices, Roy Astr Soc*, **88**, 536, 1928), on the Balmer series and associated continuous spectrum, with those of Pannekoek and Minnaert (*Verh d Kon Akad Amsterdam*, **13**, No 5, 1928) on the absolute intensity of the H_γ line, one concludes that at the base of the chromosphere there are about $2\ 2 \times 10^{10}$ ionised atoms of hydrogen and about 6200 atoms in the Balmer state, per cm^3 (Stress is not to be laid on the precise number 2 2, which is only an estimate of the order so far as it can be derived from the present state of observation and theory) Now, *were* there thermodynamic equilibrium these two numbers would be characteristic of ionisation at almost exactly 5000° K

The chromosphere is not in thermodynamic equilibrium, but I give reasons (loc cit and *Proc Camb Phil Soc*, **24**, 506, 1928) which I believe show that the various properties atomic motion, distribution among stationary states, degree of ionisation, all define temperature parameters of the same order, say, to give rather wide limits, 4000° to 6000°, which is also the order of the temperature of the incident solar radiation This agrees with the above numbers

I venture to suggest that these considerations explain why chromospheric Ca^+ at the low pressures given by Prof Milne's theory is not largely ionised to Ca^{++} Milne explains it by the removal by gravity of the Ca^{++} ions as soon as they are formed, but I believe it is due to the fact that the large excess of hydrogen ions and electrons gives the Ca^{++} ion a vastly increased chance of recapturing an electron I find that if the Ca^+ were in equilibrium at 5000° with these $2\ 2 \times 10^{10}$ free electrons per cm^3 it would be only 4 7 per cent ionised, and I conclude that the order of ionisation must be the same in actual chromospheric conditions

So long, therefore, as the hydrogen provides enough electrons to keep the ionisation of the Ca^+ fairly low, I conclude the type of equilibrium of the calcium is that given by Milne's theory But as we ascend in the chromosphere and the number of electrons decreases we expect a departure from this type to set in until, at sufficient heights, the increased ionisation prevents it holding any longer The radiation pressure on the calcium presumably then becomes negligible

These considerations support Mr Gurney's view that there must be a sharper upper boundary to the calcium atmosphere than former theory predicted They show, however, that ionisation, and not, as he tentatively suggests, the 'coefficient of partial support,' is probably the determining factor

Unfortunately, one cannot discuss the height of the

Ca^+ layer, since one does not yet know the density law of the ionised hydrogen. Pannekoek and Minnaert's work indicates it only so far as 3000 km approximately, and precludes extrapolation by suggesting that their empirical law for H_γ ceases to be valid at that height.

This work, too, it may be mentioned, gives a fairly rapid falling off of the hydrogen line intensities with increasing height in agreement with Mr. Gurney.

I attempt a discussion of the equilibrium of the hydrogen in my paper, but reach no positive conclusion.

Insects Flying to Ships.

ALL those who have travelled about the world in recent years must have noticed the insects which fly to ships at anchor, attracted by the bright electric lights. Some years ago I secured a most interesting series (including a new species of moth) off the coasts of Chile and Peru, and in many other places have made collections where I could not go ashore. The most remarkable occasion of this sort was perhaps at Diamond Harbour, on the Hooghly River, near Calcutta, in December 1927. Going up, we waited some time, and again going down (on the way to Rangoon). The latter delay was caused by a railway accident in France, which prevented the through mails from arriving in time, so we had to wait until they were brought out in a tender some time in the night. Thus the deplorable accident brought good fortune to an entomologist travelling in India—a curious example of the interdependence of things. Diamond Harbour is not really a harbour but merely a station on the river where ships anchor to await favourable conditions, with the shore distant perhaps half a mile.

The insects which came on board at Diamond Harbour were of various orders, but I will now only enumerate the remarkable series of Carabidæ or ground beetles, and a few beetles of other families, all identified for me through the kindness of the Imperial Bureau of Entomology. The Carabidæ were determined by Mr. H. E. Andrewes, the well known authority on this group.

CARABIDÆ.

Casnoidea cyanocephala Fb.
**Clivina tranquebarica* Bon.
**Tachys impressipennis* Mots.
Tachys unistriatus Putz.
Apotomus hirsutus Bates.
**Oodes westermanni* Laf.
**Diplocheila impressa* Fb.
**Diplocheila polita* Fb.
Liodaphus birmanus Bates.
**Anoplogenius microgonus* Bates.
Anoplogenius new species.
**Stenolophus smaragdulus* var. *quinquepustulatus* Wied.

Andrewes has just published a long list of the Carabidæ of Ceylon, which includes, of the above list, those marked by an asterisk. Will some of the others presently reach there on ship board, and is it possible that some already noted in both lists were carried to one or the other place on ships? Three of the above genera are at present apparently absent from Ceylon.

Some other beetles represented at Diamond Harbour were:

Cicindelidæ. *Cicindela sexpunctata* Fb.
Staphylinidæ. *Pæderus fuscipes* Curtis; *Philonthus quisquiliarius* var. *inquinatus* Steph.
Mycetophagidæ. *Litargus varius* Grouv.
Donaciidæ. *Donacia delesserti* Guér.
Haltioidæ. *Chætocnema concinnipennis* Baly.
Hispidæ. *Hispa armigera* Ol.

It is a remarkable fact that both the species of Staphylinidæ cited also occur in Britain, and *Pæderus fuscipes* also flew on to the ship when we were anchored off Sourabaya, Java, on Mar. 7. Who can doubt that these have been spread by shipping?

We have in recent years heard a great deal about the spread of insects by automobiles, but perhaps we have not always appreciated the important part which must be played by ships, now that the vessels are so large, and carry so many electric lights. I suggest that travellers, even if not entomologists, might frequently do a good service by collecting the insects coming on board, especially the beetles, which need only to be put in a small bottle of alcohol. A more ambitious but interesting project would be to take out a small vessel with a bright light and determine just how far from the shore insects of different kinds can be attracted.

Fine Structure Absorption Edges in Metals.

IT is well known from the experiments of Lindh and others that when pure metals are examined, in general no fine structure edges (as distinguished from the secondary absorption edges) are observed. If, as is generally believed after Kossel, the fine structure edges originate in the removal of the electron from the K shell to the various optical levels in the atom in question, it is difficult to understand why these edges should be absent in them. The non-appearance of the fine structure edges when metallic plates or metallic crystals (in the form of powders) are used as absorption screens can be explained on the hypothesis of the existence of free electrons in metals. The primary absorption edge originates from the removal of an electron from one stationary orbit inside the atom to another optical orbit, both these orbits possessing definite energy value.

In metallic plates the outermost electron or electrons may be supposed to be free, and as such the optical levels of definite energy values, as are usually observed in the vapours of these metals, can have no real existence. The removal of an electron by the absorption of radiation from the K shell to the periphery of the atom simply sets the electron free from the atom, and unless the former has sufficient energy it will be confined to the metal itself. The extra energy necessary to take the electron out of the metal depends on the nature of the material and the crystal lattice, and is generally of the order of 4.5 volts. Thus not only the fine structure according to Kossel will be absent in metals but also the most intense position of the white absorption will be confined to a range (of about 4.5 volts) smaller than the ionisation potential of the atom in question.

This statement is supported by the works of Fricke (aluminium and magnesium), Lindh (potassium, titanium, vanadium, chromium, manganese, and iron), and Chamberlain (titanium, vanadium, and chromium) in metals. Though we may not have fine structure edges of metal as predicted by Kossel, which should appear only in vapours of these elements, one can surely expect secondary absorption edges of these metals caused by the multiple absorption of the incident radiation by two or more electrons occupying different energy levels of the atom under consideration (see Ray, NATURE, Nov. 17, 1928, p. 771; Lindsay and Voorhees, *Phil. Mag.*, November 1928).

In vanadium metal, Lindh has observed a secondary absorption edge with a separation of 8.7 volts from the primary. Evidently this edge cannot be included under the category of Kossel's fine structure edge,

as the ionisation potential of vanadium is only 6 5 volts A rough calculation shows that this edge originates from the double absorption of the radiation by the electrons in the K and M shells, the energy value of the latter being of the order of 8 9 volts

The case of non metals and solids from this point of view will be discussed separately

Origin of the Ultra-violet Beryllium Hydride Band Spectrum

THE beryllium arc in a hydrogen atmosphere emits two band systems—one in the green region at 4800 5120 A, and the other one in the ultra violet from $\lambda 3700$ and extending as far as can be reached by quartz optics Very recently both band systems have been measured and analysed by W W Watson (*Phys Rev*, **32**, 600, 1928), and independently of this, M Peterson (*Phys Rev*, **31**, 1130, 1928) has given a short account of the green system Both investigators state that this system belongs to an electronic transition $^2P \rightarrow {}^2S$ of beryllium hydride, thus apparently corresponding to the long set of well known band systems emitted by hydrides of magnesium, calcium, zinc, cadmium, and mercury The ultra violet system was analysed by Watson only in the region $\lambda 3700$ 2700 and thus permits no definite statements regarding the pure electronic transition $n' = n'' = 0$, which falls below $\lambda 2700$ However, as pointed out by Watson, the investigation of the band $n = n'' = 0$ is necessary for information regarding the origin of the ultra violet system Watson hesitates between two alternatives the ultra violet system emitted by beryllium hydride having a common final state with the green system $^2S \rightarrow {}^2S$, or belonging to an ionised BeH^+ molecule, the transition being of the type $^1S \rightarrow {}^1S$

More than a year ago I was engaged upon an investigation of the band spectrum of beryllium oxide (*Arkiv för Mat* etc, Bd 20 A, 1928), and in the course of work was led to study the spectrum of beryllium hydride From this point of view I was interested in the two alternatives mentioned above The ultra violet system was photographed by a Hilger quartz spectrograph E_1 which gives the spectrum completely resolved down to $\lambda 2200$ A large number of bands belonging to the final vibrational state $n'' = 0$ [$0 \rightarrow 0$, $1 \rightarrow 0$, $2 \rightarrow 0$, $3 \rightarrow 0$, $4 \rightarrow 0$], were measured and analysed The values of their final rotational term differences $2\Delta F''$ definitely rule out the first alternative given by Watson Both $2\Delta F'$ and $2\Delta F''$ can be represented by the ordinary formula $2\Delta F = 4Bj + 8Dj$

The $B^{(n)}$ values so obtained are here given

$$2B'_n = 14\ 45 - 0\ 31n',\quad 2B''_n = 21\ 7 - 0\ 62n'',$$
$$(n = \tfrac{1}{2}, \tfrac{3}{2}, \qquad)$$

For the green system the values obtained from the measurements by Watson and myself are

$$2B_n = 20\ 9 - 0\ 65n,\quad 2B''_n = 20\ 5 - 0{\cdot}55n''$$

The differences in the final states of both systems, though small, are very distinct The 0 lines ($\nu_0 = P\tfrac{1}{2}$) best fit the formula

$$\nu_0 = 39417\ 1 + [1476\ 6n' - 14\ 9n'^2 - 0\ 42n'^3] - [2221\ 9n'' - 41\ 3n''^2](n = \tfrac{1}{2}, \tfrac{3}{2}, \qquad)$$

The nuclear separation of the molecule as calculated from B_0'' is $r_0'' = 1\ 31 \times 10^{-8}$ cm

From what is mentioned above I think no objections can be raised to the statement that the known systems are emitted by two different molecules As the only possible origin for the ultra violet bands there remains the ionised BeH^+ molecule This is also in agreement with the fact that the bands are formed by singlet series, the transition being of the type $^1\Sigma - {}^1\Sigma$

An Optical Method for Analysing Photographs of α-Ray Tracks

FOLLOWING a suggestion from Dr A v Hippel, of the University of Jena, I have tested the following optical method of analysing the right angle views of α ray forks The double camera for photographing α ray tracks is represented diagrammatically in Fig 1

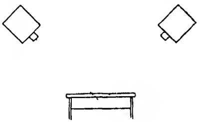

FIG 1

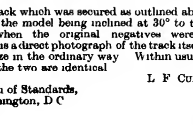
These cameras take two views simultaneously on separate negatives In order to secure a full sized image of the α ray track in the plane in which it occurred, it is only necessary to replace the developed negatives in the camera and project them on the focal plane By adjusting and rotating a thin translucent screen, a position is found where no part of the composite image appears double The screen is then in the proper plane This adjustment is very sensitive, even slight displacements of the screen from the correct position affecting some part of the image

It is very easy to secure a permanent record of the projected image of the α ray track by replacing the screen by a photographic plate A photograph thus obtained is of course actual size and should correctly reproduce all angles of the track in the plane in which they occurred Fig 2 (*a*) shows a photograph of a



(*a*) (*b*)

FIG 2.

model track which was secured as outlined above, the plane of the model being inclined at 30° to the horizontal when the original negatives were made Fig 2 (*b*) is a direct photograph of the track itself taken actual size in the ordinary way Within usual limits of error the two are identical

Solar Diffraction Spectrum from a Single Strand of Cobweb

The following account of an unusual observation of the solar spectrum seems worthy of record in the pages of Nature Recently, in brilliant sunshine, I was taking a country walk, and after walking northwards for a mile or so I turned towards the sun The dark shadow side of a hedge bank was close in front, and at once I saw—through my spectacles clearly projected against the dark bank—a brilliant vertical strip of the solar spectrum Naturally thinking this to be due either to scratches or dust on the glass, I took off my spectacles and was surprised to see a single strand of cobweb stretched horizontally across one lens between the two frame attachments, not touching the glass On replacing the spectacles and raising and lowering the head through a range of about 70° or 80° it was easy to see the first and second orders of the diffraction spectrum, and part of the third The first order appeared, violet uppermost, when the head was raised, the sun being at an angle of about 20° or 30° above the line of direct vision As the head was gradually lowered the second order commenced as a hazy light overlapping the red end of the first order, then the second order blue and green shone out brilliant and pure, and, on further lowering the head, the unusual colours produced by the superposition of the yellow, orange, and red of the second order upon the violet and blue of the third, appeared with remarkable beauty

So far, there is nothing new, for one has often seen diffraction spectra produced by scratches on a window pane, for example in a railway carriage, but the succeeding part of my observation is new to me A sudden brief period of dead stillness allowed the stretched cobweb to stop vibrating in the breeze, and then appeared brightly and definitely (though somewhat out of focus, because, though myopic, my minimum distance of clear vision is 4 or 5 inches) the familiar lines of the solar spectrum, or rather the bright spaces between the lines The strip of spectrum, which had appeared as a rectangle about ten times as long as its breadth, with clean cut edges, now appeared widened by irradiation at every bright space

Being a spectroscopist of some experience I could definitely recognise the 'pattern,' especially in the bright yellow green and in the strongly marked portion of the blue, and, as the observation was several times carefully repeated whenever a dead calm interval occurred, there can be no doubt of its reality On moving the head slightly from side to side I found that the cobweb was evidently finer and more polished in certain parts, and these parts gave a very bright spectrum with very marked alternations of light and dark

Pollination of Species of *Primula*

Darwin (1862) showed that in some species of *Primula*, which are dimorphic (heterostyled), a cross between like forms was less fertile than that between the two forms In other species the heteromorphic and homomorphic crosses are equally fertile

Primula obconica is of the first type, a short styled plant crossed with another short styled plant or a long-styled with a long styled produces no seed, while long styled by short styled and the reciprocal is fully fertile

The following facts suggest that the physiology of the relationship of male gametophyte and style is the key to the situation

Pollen of a long styled plant will not germinate upon a long style of *P obconica* Pollen of a short styled plant will germinate, but the pollen tubes will not penetrate far into the stigmatic tissue of a short style Pollen of either short or long styled plants will produce excellent tubes in the styles of opposite type Upon agar agar and 12 per cent cane sugar medium, pollen of long styled plants only germinates to the extent of 15 per cent, while pollen from short styled plants germinates to the extent of 75 per cent The succeeding growth of pollen tubes of the two types is in accordance with the germination percentages

In *P sinensis*, in which the homomorphic and heteromorphic crosses are equally fertile, the pollen tubes of short and long styled plants grow equally well on both types of style In media there is no observable difference in the behaviour of the two types of pollen

Similar work on other species is proceeding

The Electronic Charge *e*

In a letter to Nature of March 2, Dr R T Birge has pointed out the difficulty of reconciling the experimental value of 137 2 of $hc/2\pi e^2$ with Prof Eddington s theoretical value of 136 He concludes that it is highly improbable that any of the measurements of the three physical quantities involved could be so much in error The only other possibility seems to be that the value of π we calculate for practically zero field is not the value that should be inserted in obtaining the value of $hc/2\pi e^2$

It is, of course, well known that in a radial gravitational field, the value of π is less than the ordinary value Unfortunately, however, if we imagine that owing to the gravitational attraction of an electron we should use a smaller value of π in calculating $hc/2\pi e^2$ it will only make the discrepancy between experiment and theory worse In any event, the mass of an electron is so small that its effect on the value of π would be completely negligible Is it possible that the intense electric field near the electron could have the reverse effect on the value of π, and thus bring the two values into agreement? This idea may appear rather fantastic, but is perhaps worth some consideration

J H J Poole

Trinity College, Dublin

The British Museum (Natural History)

Many biologists will be grateful for the two weighty leading articles in Nature of Mar 16 and 23, on the British Museum of Natural History and on the Museums of South Kensington This letter does not purpose to discuss the important questions therein raised nor the conclusions drawn, but merely to dispel a possible confusion, which may arise in the mind of the reader of the earlier article, between editorial opinion and the unanimous resolution of the meeting of British zoologists

At that meeting, as the article in Nature of Mar 16 indicates, it was shown clearly that it is the strong and unanimous desire of zoologists that the British Museum of Natural History shall be independent of the British Museum of books and antiquities and on completely equal footing

On the desirability or otherwise of (1) changing the Trustees, (2) coming under a government department, or (3) being ruled by a council of experts, zoological opinion was shown not to be unanimous On these points no resolution was passed. Geo. P Bidder.

Cambridge, Mar 24

Co-operation in Science and Industry[1]

By Prof J F THORPE, C B E, F R S

THE past ten years have witnessed a wonderful development of organised industry and organised science in Great Britain, and although conditions are still rapidly changing it is nevertheless possible to look forward and in some measure to determine the position in which we stand and the prospects for the future The War, although one of the greatest economic disasters the world has yet experienced, gave without question a stimulus to discovery and production which no other event could have occasioned Especially was this the case in the engineering and chemical industries, for the need of new appliances and methods, and the necessity for producing in large quantities and in the shortest possible time, caused the keenest intellects to be brought to bear on the problems at hand, and led to the discovery of new and important processes many of which have now been introduced into industry

It is a principle conceded now even by the enlightened leaders of labour that the universal demand for a higher standard of living necessitates a general increase in the national productive capacity, the term 'productive capacity' being used to mean the capacity to render available the potential wealth of the nation in a suitable form It is chiefly to the chemical and allied industries, mining, metallurgy, etc, that Great Britain turns, because it is their peculiar function, aided by the engineer, to make available its mineral, vegetable, animal, and atmospheric wealth Provided chemical and allied industries are properly organised, they should be in a particularly strong position not only to increase the availability of wealth, but also to guide national policy in questions strongly affecting material prosperity The age is at hand, if it is not already here, in which the changing majorities of governments will no longer be able to determine major policies as of war, financial and fiscal, except in directions approved by organised industry Control by those who hold the keys of national prosperity, that is, of organised industry, is one of the alternatives to class control and is not only a desirable but also an eminently practicable ideal To achieve it science and industry must organise so that they may become strong politically and financially

Four kinds of co operation are essential to strength (1) internal co-operation, (2) co operation with pure science, (3) co operation with Government, (4) co operation with labour The last, that is co operation with labour, is a human question rather than one of science or of policy dependent on science and need not be further discussed, especially since enlightened opinion on the part of employers now realises that labour relations are as vital to prosperity as any other factor

[1] From the presidential address delivered at the annual general meeting of the Chemical Society on Mar 21

INTERNAL CO OPERATION

Apart from more purely chemical or scientific factors, there are two immediate advantages to be gained by the formation of big combines, in the pooling of capital and the pooling of engineering resources, the establishment of a balance in commodities produced and in the method used for their production being determined mainly by chemical and engineering conditions

The standardisation of methods and the co-ordination of interests as regards production and distribution, the question of price and the prevention of over production are problems which mainly concern the business organisation of industry, and do not directly affect the relations between industry and science Yet their importance is manifest, and in some instances, especially in connexion with the standardisation of methods, the help of the chemist is essential The need for obtaining a balance in all these factors, a consummation which can only be reached by a pooling of like interests, is obvious

Probably the best example of the common use of a chemical substance by a number of different manufacturers is that of hydrogen, which is at the present time used in vast quantities for the production of (a) methyl alcohol, (b) liquid fuels from coal, (c) ammonia, to mention three of its most recent applications In pre War days it was used in large quantities, and still is so used, for the hardening of fat Nevertheless, the three industrial operations mentioned also represent in a remarkable degree examples of progress and development that have taken place within the last ten years

At the present time we know nothing of the reasons which determine the action of a catalyst, and although we have to hand a vast number of reactions which may be regarded as reasonable and likely to occur should the right conditions be discovered, the search for a catalyst is always attended with difficulty and often ends in disappointment Prior to the original German patent for the production of methyl alcohol from carbon monoxide and hydrogen, many attempts had been made to realise this very simple reaction even on the laboratory scale

Other reactions readily suggest themselves, such as, for example, the formation of acetic acid from methane and carbon dioxide As a matter of fact, this, and other reactions of a similar type, forms the subject of patent specifications, but whether they have been actually realised experimentally must remain an open question in the absence of definite evidence Our patent system unfortunately lends itself admirably to the production of 'blocking' patents, and there is no subject so suitable as organic chemistry as a medium for such patents

Co operation with Pure Science

Training—Chemical trade is at present in the midst of the most rapid expansion it has ever known and nowhere is the development more noticeable than on the research side This is as it should be, for the researchers are the scouts and it is essential that they should be far ahead of the army (the working process) It is necessary also that the scouts should operate on a broad front in order that no channel of advance should be over looked merely because it does not lie in the ex pected direction The realisation of this principle by the greater manufacturers has led to a strong demand for university trained men, and the number of research chemists in industry in Great Britain has been estimated at twenty times the number before the War, the demand is still increasing The universities have had and are having difficulty in supplying this larger number of adequately trained men, for they have to fulfil the majority if not all the demands made by chemical industry Manufacturers have come to realise that training should be essentially fundamental and that a wide knowledge of the principles of chemical science is a necessity The vexed question in what manner is this to be attained is being answered by the gradual adoption of at least a four years' course, although the still more important one—that of the post graduate course—is not yet settled

A long experience of university teaching has shown me that it is exceedingly difficult to deter mine whether any particular individual is more fitted to succeed as a process chemist or whether he has that peculiar aptitude which will enable him to carry out effective work in the research laboratory Unfortunately, the positions are not interchangeable A student who has shown apti tude for research may, if occasion demands, make an excellent process chemist, indeed it often hap pens that he will have to elaborate a laboratory method so as to place it, with the help of the engineer, on the unit factory scale But it is very doubtful if the individual who has shown that he possesses no aptitude for research can be usefully employed in that connexion excepting under con trol The only manner in which the presence of the research aptitude can be discovered is by direct trial, and therefore it is always desirable to subject a student to one year's training in research after graduation in order to discover if he possesses this characteristic

The term research training' must be interpreted in its widest sense to include training in special branches of chemistry related to the industries as well as more general training in the higher branches of chemical technology

Industrial Research in Universities—At no far distant period in the past the great potentiality for research residing in our university laboratories, and in the personnel controlling them, was not available for industrial purposes The reasons for this were many For example, industrial research was not regarded as of sufficiently ' pure ' character to allow of its inclusion in the academic curriculum There was considered to be something essentially different between ' applied ' and ' pure ' chemistry, and this was emphasised in the 'eighties by the formation of the Society of Chemical Industry as a distinct body from the Chemical Society The Americans knew better than this They have kept their chemists together as a homogeneous body, and the American Chemical Society with its mem bership of 17,000 represents in no uncertain manner the considered opinion of the whole body of chemists of that country

The fault lay mainly with the universities of Great Britain, which were loath to introduce science other than ' pure ' into their courses of instruction Hence there arose the multitude of technical schools which were originally intended to supply the need for a vocational training without undue reference to the science upon which the training was based The establishment of new universities in industrial centres, a period of reform ushered in by the breaking up of the old Federated Victoria University, soon produced a marked change, and research and instruction in the fundamental principles underlying industrial science gradually passed into the hands most competent to deal with them

Industrial research both of the fundamental kind as well as that which arises as the daily outcome of works practice should be and now is carried out for the most part by the firms themselves in their works laboratories But there are a number of problems, mainly of a ' long sighted ' character, which are intimately related to industry The personnel on the scientific staffs of the universities of Great Britain are people who have throughout their lives specialised in some particular branch of research, and are therefore eminently fitted to solve problems in their special field This is now recognised by many leading firms who supply grants to enable post graduate research workers to investigate specific problems under the guidance of professors of chemistry and other directors of research laboratories, and in this connexion must be mentioned the far sighted policy of Imperial Chemical Industries, Ltd, which gives yearly substantial grants to research laboratories in order to enable them to obtain special types of apparatus and appliances which it would otherwise be difficult to procure

Great advances in the development of scientific industry have been made in Great Britain since the War, and every effort must be made to maintain and strengthen the causes which have led to this condition From the point of view of national prosperity it is essential that active research centres should be maintained and still further developed in our universities, not only to supply the scientific ability to foster and improve the industries of our own generation, but also to pave the way by discoveries in science for future commercial prosperity

Team Work—During the War very valuable work was accomplished by means of team work, by which is meant the solution of some problem by the united efforts of a team of workers under a directing head There can be no question that this

method of attack is usually most effective, especially in a works laboratory where some specific problem may require rapid solution. Its application to the university laboratory is subject to the difficulty that under team conditions the intellectual stimulus which attaches to the individual attack on specific problems is sometimes lacking, and it is in the highest degree desirable that this stimulus should be developed and maintained. Nevertheless, it is always possible so to divide a major problem as to make each section in itself a self contained research and thus to give each investigator what is essentially a definite subject on which he can work in his own way and according to his own mentality.

CO OPERATION WITH GOVERNMENT

The Government of Great Britain has already discovered the two most valuable ways in which it can co operate to the benefit of present and future chemical industry, namely, (a) by protecting young and struggling industries against competition from similar but established industries abroad and against competition arising from deflated foreign currency, and (b) by promoting research in pure and applied chemistry by financial assistance. Another way in which it has helped the application of science is by the provision of a free chemical advisory service in the interests of agriculture.

Research Associations —There can be no question that the value of co operative research in industry has been established. The Department of Scientific and Industrial Research has, therefore, rendered a valuable service to the industrial community and its initial policy has been fully justified. Nevertheless, the time has arrived when the varying appeal which the necessity for scientific investigation makes to different industries has made itself manifest, and the Department feels that any further support on general lines would no longer be justified. It proposes, therefore, to treat each case on its merits.

Research Studentships and Fellowships —The call for adequately trained research workers in science, and especially in chemistry, is increasing. It is therefore very disquieting to realise that the policy of the Department in connexion with the provision of maintenance grants for students in training appears to be changing. The outlook is serious, because it is quite impossible for the universities to provide funds for post graduate training in any way commensurate with the present day requirements of industry, and as the average science student is usually drawn from a comparatively poor class, it is not likely that the necessary money for an extended course will always be obtainable from parental sources.

Every director of a research school has had to tell some promising student who wishes to undergo post graduate training and is, without question, likely to profit by such training, that no funds are available to enable him to extend his course and that he must, therefore, seek any minor post that may be open to him. The loss of such a man is a national loss, because his training is broken off at the stage where even one extra year would have enabled him to become a useful member of a research organisation, whereas, in the circumstances, he has to take up some position, probably one involving merely routine work, where the value of his early training will be lost and his initiative and enthusiasm destroyed. It is therefore to be hoped that the diminution in the number of research grants is merely a temporary expedient and that it does not indicate a reversal of a policy which has proved so fruitful during the past twelve years and has shown itself to be an essential part of research development in Great Britain.

The Functions of the Human Skull[1]

By WILFRED TROTTER

THE development of science involves the two processes of collecting facts and of elucidating their relations. In the early days common experience so abounded with unrelated facts that an alert and contemplative mind was an adequate equipment for the man of science and could readily find material for generalisation. Knowledge was like an unexploited gold field, in which the mere attentive wanderer might pick up nuggets of the metal. So were made the earliest discoveries in mathematics, astronomy, and physics. When the surface of the field no longer yielded such finds, the digger with his simple and homely outfit could still from easily accessible deposits gather with his own hand gold dust by the ounce and pound. This was the Golden Age of science; it lasted somewhere about two hundred years, and was nobly marked near its beginning by the "Principia" and near its end by the "Origin of Species". It was the day of the individual digger, of simple apparatus and the still obvious predominance of the worker's mental quality over every accessory circumstance. It was a time in which relatively simple efforts in the collection of facts might have great results. Looking back at it we discern as a characteristic object Wollaston with his laboratory on a tea tray, and as a characteristic incident Hans Christian Oersted noticing in 1819 the deflection of the magnetic needle by an electric current—an experiment it would not be very extravagant to call the most important event of the nineteenth century; or as not less characteristic Joseph Fraunhofer in 1814 observing and thinking it worth while to map out the dark lines in the solar spectrum—a dull looking task that was, however, ultimately to yield a veritable measuring rod for the universe and a most effective probe of even its stupendous depths.

At the present day what we may call the surface

[1] Lecture delivered before the Anthropological Society of University College, London, on Jan. 25.

deposits of truth seem almost everywhere to have been worked over, and ours is the time of the thousand yard shaft, the mile long gallery, the battery of stamps, and the pennyweight yield to the ton The mere collection of facts has become a difficult and elaborate enterprise, to which the solitary worker is rarely equal In almost every branch of science complex equipments are necessary, the mere use of which may need years of training Even genius itself is no longer inspired by the falling apples and spouting kettles of the Golden Age, the powers of Einstein are called out by the quintessential zero of the Michelson Morley experiment, or those of Bohr by the incredible vacancies of the atom

Since the merely observational half of the scientific act has become so formidable, it is natural that the other half that comes of the speculative, contemplative, and relating turn of mind should as such have sunk somewhat in general esteem It is perhaps correct to say that, among scientific people, work of any general speculative kind is a little under suspicion unless it is closely associated with actual observation as well, and that anyone who tries to correlate large groups of facts is unlikely to be listened to with great attention unless he has been concerned at any rate to some extent in the collection of the facts themselves This attitude of the mind is on the whole sound and practical, but it should perhaps be qualified by two small reservations In the first place, the justified predominance of observation may lead to a certain frigidity towards ideas as such, and even some risk of the automatic rejection of them

In the second place, it must be remembered that there are still some few 'alluvial' deposits left unexhausted in the gold field of truth Here the observational side of scientific work may seem when judged by modern standards primitive and 'uneconomic,' and yet it may be capable of yielding appreciable finds One such deposit is the great range of human behaviour, in which we all can be adequately skilled observers and need no more than the critically selective and relating turn of mind Other such opportunities are apt to occur along the line where two fields of observation meet Medicine has many such lines of meeting with the sciences, and its contact with anthropology is one of the most obvious Medical men are interested in the same animal as are anthropologists and have to study it with some intensity

When we study the boundary zone of two adjoining departments of knowledge, we may expect to find what instruction we are to get not so much in learning strictly ordered and documented facts as in getting fresh points of view, we may hope that the well established and matter of course fact or principle from one side of the line may prove new and illuminating when viewed from the other side

In such a study, then, we shall do well not to be too exacting in proof or too systematic in method We must be willing to accept new light where we can find it, and to remember the old paradox that in science the primary duty of ideas is to be useful and interesting even more than to be 'true' We must be ready to entertain ideas freely and fairly, and no less ready to discard them without regret, glad enough when we gain an unexpected glint from "the blank face of familiar things" It will be with very limited pretensions, therefore, that certain considerations derived from surgical experience will be set out here Nothing could be less dogmatic than the spirit in which they are put forward or more submissive to the principle of the aphorism, "Do not believe new ideas, use them"

While the essential object of all biological knowledge is the elucidation of function, the work of the surgeon is actually engaged in the direct study of function in a very special degree He is concerned with the human body solely as a going concern and his unique object is to keep it going In regard to the cranium, he has no direct interest in its size, its form, its types, its indices, he limits himself, with what for the anthropologist must seem a certain crudity, to the question what does it do? In the briefest possible terms, the cranium is to the surgeon the *capsule* and *the skeleton of the brain*

The Capsule of the Brain

It is not usual to regard the brain as among the encapsuled organs, but to do so brings out an interesting aspect of its functional relations with the skull If we consider encapsuled organs in general we at once see that the rigidity of the capsule is an important character In regard to it, organs may be divided into three groups In the first, which may be called the normal type and is represented by the kidney and spleen, the capsule is fully extensible, in the second, represented by the testis, only very slightly extensible, and in the third, represented by the brain and skull, it is absolutely rigid to all physiological forces Such conditions have necessary and very important effects on the mechanics of the circulation in the various organs There is of course a primary need for the flow of blood through any tissue to be continuous, this is effected in organs of the first group by the extensibility of the capsule permitting pulsation and elastic recoil to occur In the case of the brain, however, a different mechanism is necessary The brain itself expands with each arterial pulse, but, as the skull is unyielding, room must be made at each pulsation by the expulsion of a corresponding volume of the low pressure intracranial fluids This is why the veins leaving the skull and the cerebro spinal fluid in the subarachnoid space of the spinal cord show arterial pulsation

The mechanism is adequate, but the margin by which it is so is not very large After violent exertion, when the range of pulsation of the brain is at its widest, we are apt to be conscious of an unpleasant thudding in the head, which shows that the brain can only just find room for its circulatory excursions Again, if one has a slight headache it is at once aggravated by exertion

This circulatory peculiarity is fundamental in cerebral pathology and makes it possible to say

that, apart from purely destructive processes, all cerebral symptoms are of circulatory origin

We may briefly inquire into how this comes about The low pressure outflow that must accompany each arterial pulsation is chiefly in the form of venous blood For it to occur the flow of blood in the veins must be quite free But the pressure in the veins is very low, so that the least abnormal swelling of the brain or part of it causes collapse and obstruction of a greater or less venous territory Thereupon further swelling from venous congestion occurs and the disturbance of function becomes progressive

The brain is thus uniquely sensitive to any pathological change in its bulk When an organ like the kidney is bruised and swells, it matters very little how soon or if ever it gets back to its normal size When the brain has been bruised, it must get back to its normal size or its circulation will remain permanently disturbed A simple bruise of no ultimate importance to an organ with a yielding capsule, is thus a relatively serious matter with the brain The great difficulty with which the brain recovers from even simple injuries that cause swelling is one of the most important functional consequences of its rigid encapsulation by the skull [2]

THE DEFENSIVE FUNCTION OF THE SKULL

It is still a widespread opinion, even to some extent among medical men, that fracture of the skull is the most important feature of head injury, and that if the skull is not fractured not much harm can have been done There is no more complete delusion Fracture of the skull is usually an insignificant element in a head injury, and nothing has done more to limit the knowledge of trustworthy principle than the traditional reverence for it

A fracture means that the skull has been distorted until the limit of its elasticity has been passed It is the distortion, and not the crack that may or may not ensue, that is important

Now surgical experience in Great Britain shows that the skull is susceptible to considerable degrees of distortion by even only moderately severe external violence Because immediate and dramatic effects are not always produced, and because of the superstition about the significance of fracture, it is apt to be assumed that the average European cranium is on the whole very successful in preserving the brain within it from the effects of quite severe violence Since the nature of what are called the minor injuries of the brain has been better understood, this faith in the beneficent fortitude of the skull has been considerably shaken We now know that the skull in its protective function is only moderately effective It is liable to bend under local violence and to permit of a localised bruising of the brain beneath , it is also liable in appropriate circumstances, especially such as falls on the head, to a far more serious general distortion This general distortion causes the very interesting instantaneous and transient paralysis known as concussion of the brain, and is also apt to produce a widespread bruising of the brain substance that is of great practical importance It is important to note that all the evidence points to actual distortion of the skull being the immediate cause of most if not all injuries of the brain There is no reason to suppose that injury is commonly if ever produced by the brain being thrown about inside an undistorted skull It is probably true to say in so many words, no distortion of skull, no injury of the brain [3]

This liability to relatively easy distortion seems to be in some special degree a character of the modern European skull It appears to be fairly clear that in some races the resistiveness is decidedly higher For example, the negro, judged by purely clinical, that is functional considerations, is little liable to receive cerebral contusions from the moderate degrees of violence that an Englishman could not endure with impunity The willingness of the negro to use his head as a battering ram has often been described, and it is said that an experienced policeman will use his truncheon on the head of a negro less hopefully than he would use it on an English head

We arrive then at the position that the modern European skull is demonstrably far from completely effective in its protective function, and that this defect is not shared by all other races

It will be noticed that we are not at all concerned so far with the anatomy of skulls It may or may not be possible to show a difference in the thickness or rigidity of European and negro skulls The test of function is far more delicate and trustworthy than that of structure, and it seems to show that a clear difference exists

We have already seen that the bony capsule of the brain is a serious hindrance to recovery from minor injuries, so that the skull and brain mechanism is satisfactory only when the former is highly effective as a protective covering Once the protective function is impaired the physiological disadvantages of the arrangement become fully manifest It seems clear, then, that the present functional relation of brain and skull—plainly disadvantageous as it is—must be the result of some strong evolutionary tendency or must be accounted for by some advantage that compensates for it

In a very broad and general way, it does appear to be the fact that there has been an evolutionary tendency towards a reduction in the massiveness of the human cranium , there can be no doubt that the modern European cranium is in comparison with many of its predecessors remarkably light and thin It is not improbable, therefore, that a tendency towards the lightening of the cranium is an inherent character of the race and progressive It is natural, therefore, to ask how far such a process could conceivably go The European skull has already discarded a good deal of its protective rigidity , is a rigid cranium a necessary structure ?

[2] It is interesting to notice that the testis—the only other organ in the body that approaches the brain in the rigidity of its capsule—shows the same susceptibility to minor injuries As is well known, it may undergo complete atrophy after a simple bruise

[3] A contrary opinion is perhaps encouraged by the use of the time-honoured and now ineradicable phrases concussion of the brain in English and 'Hirnerschütterung' in German

The Skeletal Function of the Skull

Without considering any other matter but function, this question can be given a perfectly definite answer However much more of its protective massiveness the skull may lose, it must always maintain enough rigidity to preserve its form This is because it is a function of the skull, not the less important for being usually overlooked, to support the brain If we make in the treatment of injury or disease a considerable hole in the skull, and after healing of the scalp is complete the intracranial tension is normal, we find a tendency for the soft parts to sink into the cranial opening This depression is most marked when the subject is standing and usually quite filled up when he is lying down With an opening 3 or 4 in across, the depression may perhaps reach a depth of as much as $1\frac{1}{2}$ in at its centre The larger the opening the greater the depression, and it is clear, therefore, that the exposed brain, when the intracranial tension is at its lowest, cannot support the atmospheric pressure and actually collapses under it In certain cases the subjects of openings in the skull suffer severely from the exaggerated movements of the brain that in them accompany changes of posture Such symptoms are always abolished when the opening is closed by restoration of the skull

In the cranium, in fact, the vertebrate has rediscovered the principle of the external skeleton and exploited it in a remarkably interesting way that may be worth a moment's consideration What may be called the constructional problems of such an immense mass of neural tissue as the brain are very complex The obvious way of supporting a large mass of soft consistence would be the provision of a stiff stroma of ordinary connective tissue Such a solution is inadmissible for very definite reasons In the first place, direct contact between mesoblastic and neural tissues is a physiological impossibility, so that every strand of the hypothetical connective tissue stroma would have to be clothed, as is every cerebral vessel, with a so called 'perivascular lymphatic' to its finest ramifications At a moderate estimate this might double the bulk of the whole organ Again, the presence of an elaborate and alien fibrous network would immensely complicate the system of intercommunication, which is the very essence of the brain as it is How neat a solution of the problem does the exo skeleton provide With it, it is possible for the brain to be made up almost entirely of actual functional elements, and for the utmost complexity of communication to exist while the bulk of the whole organ is kept within bounds

The Meaning of the Vulnerable Skull

We have seen that the low strength of the modern European skull is shown by actual experience to be producing serious effects in the way of a high susceptibility to disabling injuries of the brain To discuss the meaning of this remarkable and perhaps a little disturbing state of affairs it is necessary to enter into some rather general considerations

There can be no doubt that in the growth side by side of the cranium and the brain, the latter is the predominant partner, and what it needs the former must on the whole provide If the skull had no other function whatever but to be the capsule and skeleton of the brain, the correspondence would be absolute and every least developmental variation of the brain would be accurately accommodated by the skull Now the skull or even the cranium does have other functions to fulfil than those concerned with the brain It is involved with the muscles of the trunk, with the apparatus of mastication, with the respiratory tract The provision for these accessory needs must, it seems reasonable to suppose, have some influence however minor on the growth of the cranium, and act as some restraint however minute on the control of it by the brain, and therefore on the freedom of variation of the latter When, therefore the skull is very massive and deeply involved with accessory functions, when it gives attachment to large neck muscles, when it is ridged and fortified for a heavy masticatory apparatus, the freedom of the brain to develop minor variations is perhaps less complete than when the cranium is stripped to the condition of a mere cerebral capsule

Since it is possible that free variability of the brain through a very small range is of value in fitting man for a complex civilisation, it seems not a very extravagant supposition that the freeing of the skull from accessory functions has been a factor in human evolution

Evolution of the Brain and Skull

In considering the evolutionary process in general, then, we have to think not merely of a progressive expansion of the cranium to accommodate the increasing brain, but also of a growing independence of the cranium

It seems obvious that the anterior end of the segmental animal was the inevitable site for the chief nucleus of a centralised nervous system The same region was equally inevitably annexed for the entry to the respiratory and the digestive tracts An interesting series of complications has ensued from this necessary crowding of function into one extremity It does not seem too fantastic to see two tendencies constantly at work and in conflict—the tendency on one hand to make use of the brain skeleton for functions connected with other systems, and on the other the struggle of the brain for autonomy and freedom from these burdens Wherever the former tendency has been definitely the stronger, the progress of the brain has been arrested and the animal has found itself in an evolutionary blind alley The most striking illustration of this process has been in connexion with apparatus of defence and attack Such apparatus has a natural and inevitable localisation near the digestive inlet and at the anterior end of the animal Nature in her experiments with horns, antlers, fangs, and tusks has found the skull waiting as a

convenient foundation for these useful but enslaving structures The ancestors of man, with the steady avoidance of specialisation to which he so largely owes his zoological position, kept their craniums free from such encumbrances

It was, however, probably the beginning of the upright posture that was the decisive change in favour of the independent skull It has not, so far as I know, been much remarked upon that the upright posture changes the whole mechanics of attack and defence from that of the quadruped The head is withdrawn from the front of the animal, and thus being no longer available as a foundation for offensive or defensive structures, the cranium is at last and finally safe from them Another and more familiar way in which the cranium was helped by the upright posture to free itself from accessory functions was in the limitation in the movements of the mandible that necessarily ensued With a poised instead of a slung skull, the mouth can no longer be opened freely enough for the aggressive use of fangs Thereupon the cranium is no longer called upon to find attachment for the correspondingly massive muscles

When we see an evolutionary tendency so strong as that seems to be which has stripped and lightened the cranium until it has reached the degree of fragility and simplification seen in the modern European, we are inclined to ask whether even yet its force is exhausted There are perhaps signs that even now the cranium is, so to say, intolerant even of the light burden of accessory function it still has to bear It is scarcely possible to be familiar with the lower jaw of the modern English without wondering whether the unexhausted tendency we have been considering is not at work to free the cranium even of the temporal muscle It is clear that the molar region of the mandible is shrinking, and experience already suggests that 8 fully erupted molar teeth are nearer the actual normal than 12 Since the temporal muscle is especially concerned with the use of the molars, it is perhaps permissible to wonder whether it, rather than the jaw, is not the real object of evolutionary attack

The tenuity of much of the foregoing speculation must be obvious The argument, however, makes no attempt to be rigorous, and is intended to be illustrative rather than demonstrative The object of it has been to find out whether the old fashioned method of general qualitative survey might not in so favourable a situation as the frontier between two branches of knowledge, present the familiar facts of one side of the line in a way that would have freshness and perhaps interest on the other

News and Views

THE Postmaster General has written an excellent letter, dated Mar 27, to the Baird Television Development Company He states that he has seen a demonstration of the Baird system and that he could recognise with sufficient clearness the features and movements of persons posed for the purpose in the transmitting studio He is a little doubtful whether it is at present practicable to reproduce simultaneously more than two or three individuals, and they must be staged in very close proximity to the transmitting apparatus In his opinion the Baird system represents a noteworthy scientific achievement Taking into consideration the present limited scope of the objects which can be reproduced, he does not consider that it is at present practicable to include television in the broadcasting programme in broadcasting hours He is anxious, however, to give facilities so far as practicable without impairing the broadcasting service for continued and progressive experiments to be made with the Baird apparatus He consents to a station of the British Broadcasting Corporation being utilised for this purpose outside broadcasting hours The Company would probably have little difficulty in negotiating satisfactory terms with the Corporation It is very desirable that experimental demonstrations of television should be accompanied by the broadcasting of speech Consequently, two wave lengths and two transmitters are required It would be very difficult to provide a second transmitter in a suitable locality which would not interfere seriously with important radio services in central London, until the new station of the B B C at Brookmans Park be opened next July In the mean time, the engineers could jointly discuss the best methods In order to get a television service during broadcasting hours, wave lengths outside the bands now being used for speech broadcasting must be used Unfortunately, these bands are much congested It is important, therefore, that the Company should press on with experiments on as low a band as possible Purchasers of receiving apparatus are warned that they buy them at their own risk, as the system is not yet sufficiently advanced to warrant giving it a permanent place in the broadcasting programmes

IT is interesting to learn from a *Daily Science News Bulletin*, dated Feb 26, issued by Science Service, Washington, D C, of the paternal attitude adopted by the Federal Radio Commission towards the many applicants who are anxious to start television broadcasting in the United States Eleven licences for television broadcasting have already been granted, but in all cases precautions have been taken that such activity is for a limited period and is purely experimental The licences are only for six months The broadcasters have to give monthly reports of their activities and of the scientific work they are doing to advance the art The Commission apparently is not yet convinced that radiovision can render real service comparable, for example, with that of sound broadcasting They are naturally anxious to prevent anyone broadcasting radiovision with the main purpose of selling radiovision receivers The Commission has allotted to radiovision, or, as they call it, 'visual broadcasting,' which includes still pictures, 'radiomovies,' and pictures of living actors, four bands of frequencies

The first two bands are between 2000 and 2200 kilocycles (136 150 metres) and the other two bands are from 2750 2950 kilocycles A further band between 2200 and 2300 kilocycles for radiovision may also be used in the future provided that it does not interfere with Canadian stations The present radiovision broadcasting stations are situated in New York, New Jersey, Washington, East Pittsburgh and Springfield, Mass, Schenectady and Oakland in California Many applications are still pending, and hearings will be held to determine "whether or not public interest, convenience, or necessity would be fulfilled by granting their applications" No television broadcasting (that is, by wire) will be allowed on any frequency in the broadcast band, except between 1 A M and 6 A M

AT a recent meeting of the Royal Statistical Society, Dr E C Snow, who read a paper on "The Limits of Industrial Employment," said that before the War the population of Britain was increasing by about 350,000 a year, but now the annual increase is not much more than half this figure In ten years time it is estimated that the increase will not be much more than 100,000 per annum Important changes have taken place in the age distribution of the population In the decade before the War, 130,000 of the annual increase occurred in the age group 30 45 (probably the most important period of life as regards the demand for goods for consumption) and only 50,000 in the group above 60 At the present time the former group is increasing by only 30,000 per annum, while those over 60 are increasing by more than 100,000 per annum These changes, Dr Snow said, are of importance in the study of the unemployment problem Modern industry requires a continuously expanding market since many workers are engaged in manufacturing machinery and other capital goods which will help to increase future production But if population does not increase correspondingly, a state of over production will arise and this will react on the employment capacity of industries which produce capital goods or their raw materials The effect on employment is cumulative, because those who manufacture capital goods are themselves consumers, and their demand as consumers will be reduced The effect is the more severe in Britain because this country is far more dependent upon industrial activity for employment than any other

ON April 6 occurs the centenary of the death of Niels Henrick Abel, the brilliant young mathematician who died at the early age of twenty six Born at Findoë, Norway, on Aug 5, 1802, the son of a minister, Abel was educated at the Cathedral school and University of the capital, and from the age of sixteen gave evidence of striking mathematical powers After the death of his father he was supported by the professors, and later by a pension from the government He travelled into Germany, Italy, Switzerland, and France, became intimate with Crelle, but it is said that his visit to Paris proved disappointing After his return to Norway, however, Legendre, Poisson, and Lacroix wrote to the King of Sweden on his behalf, but no notice was taken of the letter, and a few months later Abel died of consumption at Arendel "The great point," said De Morgan, "to which Abel turned his attention was the theory of elliptic functions Legendre, who had devoted a large portion of his life to the development of these functions and the formation of tables by which to use them, found himself, when his toil was just finished, completely outdistanced by the young Norwegian of whom no one had ever heard" The centenary of Abel's birth was celebrated with great enthusiasm at Oslo in September 1902, when honorary degrees were conferred on many men of science, among whom were Kelvin, Rayleigh, Salmon, and Stokes, while in 1908 a striking monument to him was erected close to the University building

THE differences of opinion which have arisen on the subject of the management of the New Forest have already been alluded to in NATURE The Forestry Commission, on taking over the Crown Forests from the Woods and Forests branch, commenced certain sylvicultural operations in the Forest without reference to local opinion—operations which were viewed with alarm by a certain section of the public The ideas of this section were powerfully voiced by the New Forest Association, which represents, amongst others, the right and privilege holders (i e the commoners) In how far the New Forest Association can claim to voice the opinion of the general public is open to doubt It is this view of the question which Mr H H Haines, a well known botanist and formerly a member of the Indian Forest Service, considers in a small pamphlet which he has prepared and circulated to the members of the Society for the Promotion of Nature Reserves, fellows of the Linnean and Royal Societies, and others Although we are not in agreement with all Mr Haines's contentions, he presents the case for a correct management of the New Forest in a perfectly straightforward and fair manner If the absence of all efficient management which has persisted for many years is maintained, the most beautiful parts of the Forest are doomed to disappear Professional opinion is at one on this matter Since Mr Haines can speak on the sound professional side, whilst being at the same time a botanist and a Nature lover, his small brochure, which unfortunately bears no title, should be read by all lovers of the New Forest

IN the Final Report of the Committee on Industry and Trade, which has recently been issued (Cmd 3282 London H M Stationery Office, 1929 *5s 6d* net), considerable stress is laid upon the benefits which would accrue to industry in Great Britain from the greater recognition of the value of scientific research In certain other countries, notably Germany and the United States, a very great amount of research is carried out by various industrial associations, corporations, and combines, and even by large individual concerns, though in Britain the importance of scientific research is imperfectly realised by the leaders of industry In the opinion of the Committee, a change in this attitude would open up prospects to British industry which at present are beyond the

range of possibility It is true that certain large works in Britain carry out much research work, but for the most part this consists of mere routine testing, or what has been called 'tactical' as distinguished from 'strategical' research, that is, the improvement of results obtained from a given process or the investigation of fundamental laws The latter has to be undertaken by the State or by co operative research associations which represent a joint effort of the industries themselves and the Department of Scientific and Industrial Research The Committee suggests that the most hopeful direction of future development is to define more and more clearly the line of demarcation between the kind of research which is the special function of the State, namely, that concerned with fundamental scientific problems and their application to industry as a whole or to great groups of industries, and that which is the proper function of industrial undertakings either singly or in co operation

THE Committee finds most cause for disquietude in the relations between the research associations and the industries themselves, since the response to the propagandist efforts of these associations is frequently most disheartening, even when full allowance is made for difficulties such as trade depression and the expense of installing new plant and processes It recommends that every important trade association should take into consideration the existing means of disseminating technical and scientific information and, where these are inadequate, should take steps to establish suitable machinery for the purpose The research associations on their part should engage in a campaign of publicity and explanation in order to popularise their results There should be some responsible, suitably qualified officer on the staff of each firm, whose duty it would be to follow the progress of scientific research as summarised in the bulletins received It is also essential that at least an adequate proportion of the responsible heads of industry should have the scientific habit of mind, though it is not necessary that they should themselves be trained researchers "Before British industries, taken as a whole, can hope to reap from scientific research the full advantage which it appears to yield to some of their most formidable trade rivals, nothing less than a revolution is needed in their general outlook on science and in the case of some industries at least, this change of attitude is bound to be slow and difficult, in view of our deeply rooted industrial traditions"

THE wireless organisation for the air mail service to India, which opened on Mar 30, is such that the aircraft engaged will be in touch with aerodrome ground stations throughout the 4700 air miles of the journey On the London to Basle section, the present wireless organisation for continental aviation will be employed The aircraft are fitted with Marconi sets of 150 watts power (Type AD6), adapted for communication over distances of 200 to 300 miles either by telephony or telegraphy From Basle the night train to Genoa makes the connexion with the second section of the air route, from Genoa to Alexandria, operated by three 'Calcutta' flying boats fitted with the more powerful Marconi Type AD8 sets These sets are also adaptable for telegraphy or telephony, enabling the pilots to keep in touch with Italian and British Air Ministry wireless stations until arrival at Alexandria In addition, Imperial Airways, Ltd, which is conducting the London Karachi service, has stationed a depot ship in the Greek Archipelago This has been fitted with a Marconi valve transmitter of ½ kilowatt power (Type U) and suitable receiving equipment (Marconi Type RG19 Receiver), and will be capable of communicating with Malta, Alexandria, and other stations concerned with the service At Alexandria a change is made to aeroplanes again for the final section of the route, through Basrah and over the Persian Gulf to Karachi Part of this section has been in operation for some time, employing De Havilland aircraft fitted with Marconi AD6 apparatus and communicating with R A F stations and a ½ kilowatt station at Rutbah Wells During the flight from Basrah to Karachi, the machines will be in touch with two Marconi stations in Persia, at Chabar and Bunda Abbas The terminal wireless station at Karachi is one of the most powerful aerodrome stations installed at any air port, consisting of a 6 kilowatt Marconi transmitter with direction finder receiving apparatus Many features of the Marconi apparatus for this service have been specially designed to meet the conditions existing on this new route

AT the meeting of the Illuminating Engineering Society on Mar 19 a paper on architectural lighting was read by Mr Waldo Maitland The author defined this term as implying that the lighting becomes an essential part of the architectural scheme, and in some cases the major element Amongst the devices adopted, luminous panels in the ceiling and walls, lighted columns and lintels, and cornice lighting were mentioned, but in the examples shown by Mr Maitland, which included a number of original lighting schemes adopted in Paris, many other novel methods were illustrated This mode of lighting has been adopted at present mainly in the case of large stores, restaurants, and places of entertainment, but it has evident possibilities in modern buildings of architectural distinction Naturally these methods, which involve the reflection of light from diffusing surfaces (concealed lighting) or its transmission through more or less dense translucent glass, may require a higher consumption of energy than do conventional methods But in many cases a sacrifice in efficiency might be tolerated in order to obtain the desired picturesque effect Complete success, however, can only be obtained when the co operation of the lighting expert and the architect can be secured in the early stages of the design of the building At the conclusion of the meeting a series of demonstrations were given in the architectural lighting room of the E L M A Lighting Service Bureau, various pleasing combinations of lighting from artificial skylights, cornices, luminous bands encircling the room, and luminous lintels and doorways being shown The underlying idea is based on the recognition that whereas the buildings of the past were designed solely with a view to appearance by daylight, appearance by artificial light is now

frequently of equal importance This consideration may materially influence the architecture of the future

ALTHOUGH little is now heard of Tutankhamen in the daily Press, the tomb continues to provide from its store a wealth of objects both of intrinsic beauty and of interest to the student of Egyptian culture In the *Times* of Mar 30 is given a long list of articles from it which have recently been added to the Cairo Museum Some of these are unique and many of unusual type Among these is the only existing example of the well known sickle sword known as 'Khepeth' with which the King slew his enemies A model sickle of wood inlaid with gold in the shape of the jaw bone of an ass has red, blue, and purple glass in place of the more usual serrated edge of flint Especially interesting are head rests of an entirely new form One is of blue faience with gold and polychrome glass, another of light blue glass, and a third is made like a three legged stool with legs ending in goose feet and with a grotesque figure of the god Bes with its tongue out on top Boomerangs include some apparently of the returning Australian type and unlike the Egyptian throwing stick type Another object which is unique is the King's game board It is made of polished ebony marked off into 30 squares, of which some are marked with hieroglyphs The pawns are of faience, and in a drawer in the board were two ivory knuckle bones and dice in the form of sticks, black on the one side and white on the other Miniature boards of the same kind were also found Of special interest to technologists were a wicker basket covered with linen on which were a design in yellow, blue, red, and white beads, and a pattern of beads representing captives on top, and a bow fire drill with which was a piece of wood bored with twelve holes and marked with charring, which had apparently been used with the drill for producing fire

A NOTABLE extension of the Manchester Museum is recorded in the *Report* for the year 1927–28 The Haworth Extension Building, which now becomes the centre and main entrance of the Museum as a whole, was erected at a cost of approximately £29,000, and £5000 has been spent upon cases and fittings The Haworth benefaction, a handsome gift, to which the extension was due, provides a further £1100 for additional cases, and a sum of £15,000 as a permanent endowment Formally opened by Mrs Jesse Haworth on Nov 28, 1927, the building has been devoted to the exhibition of ethnological collections in a series of alcoves, which serve to emphasise the geographical and racial human groups, while room has also been found for comparative series of weapons and utensils Of the six floors of the building, the top and the basement, more than a third of the available area, have been allotted to work rooms and the storage of study collections—a welcome indication that the needs of the student as well as of the ordinary museum visitor are being kept well in view The removal of the ethnographical collections has permitted an expansion of the natural history collections, and the rearrangements thus made necessary are now in progress It is an excellent sign of the place taken by the Museum in the education of the city that the Education Authority has delegated five teachers to conduct school classes in the galleries, to the extent of a hundred classes weekly, and the rearrangement of the collections will now enable these teachers to be provided with special rooms for their class work

THE generally admitted superiority of American monthly journalism is challenged by a new monthly, entitled *The Realist*, the first number of which was published by Messrs Macmillan and Co, Ltd, at the end of March This journal is to be devoted to science, industry, art, and economics, and the general editor is Major Archibald Church An editorial board has been appointed, on which the interests of science are represented by such names as Prof F G Donnan, Sir Richard Gregory, Mr J B S Haldane, and Prof Julian Huxley The new magazine stands for scientific humanism, and we are invited editorially to test its scope by an examination of the subjects and writers of the articles published in this first issue Literature is represented by Arnold Bennett, who writes on the progress of the novel, and by Aldous Huxley, who writes on Pascal Among the subjects of articles of scientific interest are "Rejuvenation" by Norman Haire, "Science and the Farmer" by Sir Daniel Hall, 'Scientific Humanism' by Dr Charles Singer, and other articles deal with architecture, music, and the movies' *The Realist* is excellently printed and produced, and if the high standard set by the first number is maintained the journal will soon secure wide recognition

THE non magnetic yacht *Carnegie* arrived at Papeete, Tahiti, on Mar 13 Conditions throughout the passage from Callao, Peru, were excellent On Feb 16 the soundings obtained showed depths from 2700 metres to 5400 metres and back to 4100 metres over a distance of 50 miles, the ocean deep thus revealed was named 'Bauer Deep' Two uncharted submarine ridges were also discovered and rapid slopes off Tatakoto and Amanu Islands were determined On Mar 8 five hours were spent ashore on Amanu Island The bottle sample obtained at 2100 metres on Mar 10 (latitude 17° 6 south, longitude 141° 9 west) contained a few fragments of black lava with no trace of ooze, indicating recent volcanic origin The work done on this passage included 63 determinations of magnetic declination and 17 of magnetic intensity and inclination, 17 ocean stations, at 15 of which bottom samples were obtained, 206 soundings, 35 pilot balloon flights, one of which was followed to a height of more than 6 miles, 8 determinations of evaporation, 4 series of atmospheric electric observations by eye readings, each throughout 24 hours, and 23 complete 24 hour photographic electrograms of potential gradient The vessel left Papeete on Mar 20 for Apia, Western Samoa, she will also make a short stop at Pago Pago, American Samoa

HIS Royal Highness the Prince of Wales has consented to become patron of the Society for the Preservation of the Fauna of the Empire, which was founded in 1903 by a group of animal lovers with the object of awakening public interest in the great heritage of wild life existing all over the British

Empire It has a very energetic president in the Earl of Onslow, and has helped in the formation of the many sanctuaries and national parks which are now to be found throughout the Empire There is, however, much more work to be done in this direction, and the Society needs further support in order that it may continue to carry out its objects efficiently The Society's secretary is Col J Stevenson Hamilton, well known for his work in the formation of the Kruger National Park recently opened in South Africa Further information about the Society can be obtained from the secretary, S P F E, c/o Zoological Society, Regent's Park, London

HIS Royal Highness the Prince of Wales has consented to become an honorary member of the Linnean Society of London

WE much regret to announce the deaths of the Right Hon Lord Avebury, on Mar 26 at the age of seventy years, and of Lord Montagu of Beaulieu, K C I E, C S I, on Mar 30 at the age of sixty two years Lord Avebury was a trustee and also the honorary treasurer of the British Science Guild, and Lord Montagu was president of the Guild in 1920–22

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A government chemist in Fiji—The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, Whitehall, S W 1 (April 10) A lecturer in metallurgy at the Technical College, Bradford—The Principal Technical College, Bradford (April 12) An assistant lecturer in preparing, combing, and spinning and yarn manufacture at the Bradford Technical College —The Principal, Technical College, Bradford (April 12) An established analytical chemist, Class II, in the Royal Naval Cordite Factory, Holton Heath, of the Scientific Research and Experimental Department of the Admiralty—The Secretary to the Admiralty (C E Branch), Whitehall, S W 1 (April 13) A fellowship in the department of Coal Gas and Fuel Industries of the University of Leeds for post graduate research in gas chemistry—The Clerk to the Senate, The University, Leeds (April 19) A senior chemist under the Northern Coke Research Committee, Armstrong College—Prof H V A Briscoe, Armstrong College Newcastle upon Tyne (April 22) A director of the Dental Prosthetic Laboratory, Guy's Hospital Dental School—The Dean, Guy's Hospital Dental School, London Bridge, S E 1 (April 30) A professor of imperial economic relations, tenable at the London School of Economics—The Academic Registrar, University of London, South Kensington, S W 7 (April 30) A head of the Navigation Department of the L C C School of Engineering and Navigation, Poplar—The Education Officer (T 1a), County Hall, Westminster Bridge, S E 1 (May 13) A government analyst, Cyprus—The Private Secretary (Appointments) Colonial Office, 2 Richmond Terrace Whitehall S W 1 An assistant editor of *Science Abstracts*—The Secretary Institution of Electrical Engineers, Savoy Place, W C 2

Our Astronomical Column

STUDIES OF PROPER MOTION —Prof J Comas Sola, of Fabra Observatory, Barcelona, contributes an article on this subject to *Scientia* for March It begins with a historical review of the subject, and goes on to describe the modern methods of picking out stars with sensible motions by means of the stereocomparator This is essentially a stereoscope in which plates taken at an interval of a few years are viewed simultaneously by the two eyes Prof Sola has devised an improved form in which the plates can be rotated so that the displacement due to proper motion of the two images of any star is parallel to the line joining the eyes He states that an interval of 20 days between the exposures suffices to give a sensible displacement in the case of 61 Cygni, the motion of which is 5 2″ per annum The focal length of the camera employed is only 80 cm He makes a comparison with the 'blink' micrometer, but considers his instrument superior Work of this kind is very useful for detecting faint stars with appreciable proper motion

WOLF'S PERIODIC COMET —Prof M Kamiensky, Director of Warsaw Observatory, has been engaged for many years in a detailed study of the perturbations of this comet from the date of its discovery in 1884 to the present time At the aphelion passage between 1918 and 1925, it approached very closely to Jupiter and suffered large perturbations that increased its perihelion distance from the sun by nearly a unit These enormous perturbations were so accurately computed that the comet was found close to the predicted position

Acta Astronomica for January 1929 contains a careful recomputation by Prof Kamiensky of the perturbations between 1891 and 1898 He had previously used A Thraen's results for this revolution, but finding that he did not use the latest values for the planetary masses Prof Kamiensky has repeated the work with the greatest care, carrying the work to units of 0 001″ The differences from Thraen, after allowance has been made for the different masses employed, are very small But it was necessary to repeat the work to obtain the degree of accuracy necessary to link together all the apparitions of the comet in a rigorous manner

CLUSTERS OF UNIVERSES — It has been long known that there is a rich nebulous region in Virgo and Coma Berenices, close to the north pole of the galaxy The nebulæ in this region are of the type which Dr Hubble's researches marked out as external galaxies, so that we have evidence that these objects are not scattered uniformly but are aggregated more densely in some directions than in others In *Harvard Bulletin*, No 864, Prof Harlow Shapley and Miss A Ames show that, in addition to the main assemblage, the distance of which is given as about 10 million light years, there are three other adjacent 'clouds of galaxies' these are fainter and smaller, so are probably much more remote The correlation between magnitude and angular diameter indicates the relation $m = 24\ 15 - 5 \log d$, where m is the apparent magnitude and d the diameter in seconds This equation would indicate the perfect transparency of space the departure from it is so small that it is estimated that the loss of light through absorption in space does not exceed one fifth of a magnitude in a hundred million light years This of course is not true in the special regions in our galaxy where there is strong evidence of local absorption by dark matter, as, for example, in the 'Coal Sacks'

Research Items

Witchcraft in Southern India.—In *Man* for March, Mr. F. J. Richards publishes photographs of houses in Arantāngi, Tanjore, which have been demolished by their owners in their fear of 'black magic'. On the occasion of a visit to the village in 1900 he found the Brahmins in a panic, stripping the thatch from the roofs of their houses and removing their belongings into the street. On the previous night no less than seven houses had been set on fire by supernatural agency, and the whole Brahmin quarter had been pelted with stones thrown by invisible hands. Stone-throwing continued in broad daylight, and when another fire broke out the householder brought to the author a rag ball a little bigger than a tennis ball which had been found under the eaves. Tow and rag had been rolled tightly together. It was damp and was said to smell of phosphorous, though this was not perceptible. In the centre was a small fruit stone—held by the villagers to be conclusive evidence of sorcery. The kitchens were desecrated with blobs of boiled rice, coloured yellow or magenta, and mixed with clippings of human hair and nail parings. These were found secreted in and about the cooking places. This defilement of places of which the ceremonial cleanliness is of the utmost importance, was especially to be noted. The Brahmin quarter was the residence of the most intelligent and prosperous section of the village. It was suggested that blackmail was the origin of the visitation. Some professed expert in sorcery had demanded a contribution from each household and had been refused. This was his retaliation.

A Pile Dwelling at Brentford.—In *Antiquity* for March, Dr. R. E. M. Wheeler describes some investigations recently carried out on the foreshore and in the bed of the Thames at Brentford. In 1928 public attention was attracted by the frequency with which bronze weapons and implements were found in the neighbourhood, and especially near the meadow "Old England" just above the junction of the Thames and the Brent, particularly through the collections made by Mr. G. F. I. Lawrence. Mr. O. G. S. Crawford has suggested that this may be the site of one of a number of settlements of lake dwelling peoples from Switzerland of the late Hallstadt Iron Age. A fund was raised for excavation through the *Daily Express*. The result was the discovery of a Romano-British pile dwelling—the first of the period recorded in the British Isles. As the excavations were below tide level they were carried out under great difficulty and only part of the site was uncovered. This, however, was sufficient to indicate the existence of a rectangular dwelling. Piles were found in position with part of the floor of the hut. The first indication of the date of the structure was a complete Roman pot found above this floor. The structure of the floor was as follows. A pile was driven more than three feet into the gravel—how much more it is impossible to say; a horizontal beam was laid on the pile on the level of the gravel; then a layer of green clay was laid on the gravel to the height of the beam—6-7 inches. Upon this was laid a longitudinal layer of wattle. Upon this was a second horizontal timber and then a further layer of clay. A double layer of wattle formed the final floor, nearly 2 feet above the gravel. The timbers were unsquared. A Roman roofing tile beneath the wattle floor in the upper layer indicated the period. Roman pottery and roofing tiles were found around the hut. In the surface of the gravel, fragments of coarse pottery were found which can with confidence be assigned to the half millennium 1000-500 B.C., known in Central Europe as 'Hallstadt'.

Photosynthesis in the Sea.—The Annual Report for 1927-28, drawn up by the executive to the council of the Scottish Marine Biological Association, shows a satisfactory financial situation, the greater part of the expenses of the marine research being defrayed by the Development Fund of H.M. Treasury, together with an amount contributed from local sources. Miss S. Marshall and Mr. A. P. Orr having been granted leave of absence in order to join the Great Barrier Reef Expedition, temporary appointments have been made to fill their places. Before leaving, their researches on photosynthesis in the sea had been continued, including further experiments on diatom cultures enclosed in glass bottles suspended at different depths in the sea, the oxygen produced being measured. From the results it was concluded that the light intensity at which photosynthesis just balances respiration in these inshore waters is never deeper than 20-30 metres even in summer. As the surface is approached the increasing light enables more photosynthesis to take place, but this increase only goes up to a certain depth, above which the light is too strong. During the spring maximum the diatoms are so numerous that they shut off a considerable amount of light and the compensation point rises. Different species behave in different ways. The members of the genus *Chætoceros*, summer forms in these regions, were found to be more sensitive to sunshine than those of *Coscinodiscus*, which are chiefly spring forms, both in cultures and naturally in the sea. Two papers have been published by these authors in the *Journal of the Marine Biological Association* in 1927 and 1928, "The Relation of the Plankton to some Chemical and Physical Factors in the Clyde Sea Area" and "The Photosynthesis of Diatom-Cultures in the Sea."

Decapoda of the *Siboga* Expedition.—Dr. J. G. De Man has continued his studies of the rich material of the *Siboga* expedition, his latest report dealing with the Thalassinidæ and Callianassidæ (*Siboga* Expeditie Monog. 39 a6, Leyden, December 1928). This report, which amounts to a partial monograph of the group, gains particular value from the list of species known in each genus and the tables for their identification. The *Siboga* material includes 10 species of *Upogebia*, of which 5 are new, and 15 of *Callianassa*, of which 12 are new. This large proportion of new species shows how little those burrowing forms are known. Dr. De Man illustrates this point by saying that, out of 76 species of *Callianassa* described, 46 have not been seen since their description. No one to this day knows the manner of life of *Jaxea nocturna*, which has been known since 1818. Its larva is commonly met with on the coasts of Britain, but the adult has been taken only twice. There is one omission from this report which is difficult to understand—*Naushonia crangonoides*. In one of his earlier reports, Dr. De Man includes it among the Crangonidæ, but he does not mention it here at all. There is no doubt whatever that it is not a crangonid but a thalassinid, and it is almost certain that it is closely related to *Jaxea*. The author does not enter into the question of the phylogeny and systematic position of these remarkable and probably very ancient Decapoda; but his extraordinarily detailed description of the species will be valuable material with which to build. The last word has certainly not been said as to the position of the Thalassinidea among the decapods or their relation to one another.

A Japanese Oligochæte.—Mr. Hironori Yoshizawa gives an interesting and detailed description of

the freshwater oligochæte *Stylaria lacustris* which is very common in the pond of the Biological Laboratory, Tôhoku Imperial University ("On the Aquatic Oligochæte *Stylaria lacustris* L." *Science Reports of the Tôhoku Imperial University*, 4th Series (Biology), Sendai, Japan, vol 3, No 4, Fasc 1, 1928) The worm is remarkable in having an elongated prostomium It was cultured in the laboratory, the cultured specimens being used for the present work These all attained sexual maturity in early autumn, September and October being the natural time for the sexual form in the pond The food consists of diatoms, other algæ and vegetable debris One of its enemies is *Hydra*, which swallows the worm, helping it down with its tentacles (body length of the worm 8 11 mm) This reminds one of *Protohydra*, which can swallow oligochætes much longer than itself, and in that case with no tentacles at all Asexual forms are found in spring These are rather shorter and thinner than the sexual worms and fission may take place in three or even in four places The front portion forms a new tail by adding a number of posterior segments, and the hind portion adds five new segments anteriorly to form a new head As a rule, fission proceeds from the ventral plane, midway between the anterior and posterior septa of the segment There are usually twenty five segments, 16, 17, 18, 19, and 20 being the segments which most frequently undergo fission

LIVING FORAMINIFERA IN THE TRANSCASPIAN KARA KUM — Up to now only a few marine Foraminifera have been found in fresh waters or in continental waters generally Some marine genera (such as *Polystomella*, *Rotalia*) come up to river estuaries and small freshwater lakes by the sea In the spring of 1927, A L Brodskii (*Priroda*, No 11, 1928) found a numerous fauna of Foraminifera in the wells of the Kara Kum desert These wells lie north east of Askhabad, their depth is 18 20 m , temperature of the water in spring is 17° 20° C , and in some cases the water contains as much as 10 gm of salt per litre The Foraminifera found in the wells belong to the genera *Spiroculina* (a new species *turcomanica*), *Biloculina* (*B elongata* and a new species *turcomanica*), *Textularia*, *Nodosaria*, and *Lagena* They all contained protoplasm, and in some a nucleus or nuclei were found , thus there can be no doubt that they were alive All the Kara Kum Foraminifera are very small in size , whilst the marine *Spiroloculina* and *Biloculina* reach 2 3 mm in length, the Kara Kum representatives of the genera scarcely exceed 0 16 mm Their shells are fragile, transparent, flattened, and smoothed They evidently inhabit salty ground waters of the sands of Kara Kum desert, whence they fall into the wells They are probably relics of the Upper Tertiary seas which once covered the Kara Kum desert Waters of the Sarmatian and the Akchaghyl seas may also have stretched up to there It should be noted that *Polystomella*, *Rotalia*, *Textularia* are still found in the Caspian Sea Masses of valves of *Polystomella* and *Discorbina* are found in the Aral Sea, and it is probable that Foraminifera live there now

REVISION OF THE GENUS TRIGONELLA —In his monograph on the genus *Trigonella*, G Sirjaev proposes a new division of the genus into three subgenera, fifteen sections and numerous subsections The first published part (*Publications de la Faculté des Sciences de l'Université Masaryk*, No 102, 1928) deals with the taxonomy and distribution of twenty one species of the chief subgenus *Trigonella*, one new species from Bokhara and several new varieties being described

WATER METABOLISM IN DUSTY LEAVES —With most plants the transpiration of dust covered leaves is considerably lower than that of leaves which have been recently cleaned, so that after a few hours the former leaves will contain appreciably more water than the latter An exception to this general rule, noted by Luigi Montemartini in the *Rendiconti* of the Royal Lombardy Scientific and Literary Institute (vol 61, parts 11 15), is observed in the case of *Ceratonia siliqua* (L) Here the cleansed leaves, although exhibiting a markedly more active transpiration, yet accumulate more water than those covered with a layer of road dust To explain this exceptional behaviour reference is made to the fact that as Bose showed, transpiration renders more active the circulation and ascent of water in plants, whereas diminution of the transparency and of the permeability to gases of the cuticle by the thin coating of dust determines a decreased production of substances able to retain moisture in the cells It would seem that, with *Ceratonia* leaves, the cuticle presents peculiar features as regards this transparency and permeability and the cellular protoplasm a sensitiveness which under the conditions employed, leads to a retardation of all the vital functions with consequent loss of water when the leaves are dust covered

CYTOLOGY OF ŒNOTHERA —A useful summary of our knowledge of the cytology of *Œnothera* has been published by Prof R R Gates in *Bibliographia Genetica*, 9, 401 (1928) It was in this genus that important correlations between chromosome content or behaviour and genetic phenomena were first discovered Since the original announcement of chromosome numbers in *Œnothera* was made in December 1906 an enormous amount of research has been carried out on many of the species, mutations and hybrids of wild and cultivated evening primroses as is indicated by the bibliography of seven and a half pages attached to this paper, which summarises work up to 1923 with some references to subsequent publications Chromosome numbers in 30 species are now known The improvements in cytological technique in recent years have led to the demonstration of delicate connexions between the ends of the chromosomes, and these determine the peculiar alinement observed in the heterotypic metaphase The meiotic process is certainly telosynaptic The mutant *Œ gigas* was the first investigated tetraploid mutation The first examples of non disjunction were also studied in this genus, and double non-disjunction is now known to occur Trisomic mutations, with 15 chromosomes, are the most characteristic of all the mutations of *Œnothera* and include the well known *Œ lata*, *Œ scintillans*, *Œ oblonga* and *Œ albida* The view that *Œ lamarckiana* is, in spite of the numerous mutations it has thrown, a persistent species of equal value to *Œ biennis* and others of the *Onagra* group, is maintained, though it is suggested that the whole group may be ultimately hybrid in origin Indeed, it is accepted that hybridisation followed by new chromosome linkages and accompanied by mutations, some of them cytoplasmic and some arising in the chromatin, have been largely responsible for the evolution of the genus *Œnothera* as we now know it

THE PARKGATE SEAM IN SOUTH YORKSHIRE —The Department of Scientific and Industrial Research has issued the thirteenth of its physical and chemical surveys of the coal resources of Great Britain (London H M S O , 1929), being an investigation of the Parkgate Seam, which occurs over an extensive area in South Yorkshire and the adjoining parts of Nottinghamshire and Derbyshire The seam is an exceedingly

important one and extensively worked throughout the whole area in question In Derbyshire and Nottinghamshire it is spoken of as the Deep Hard, whilst in Yorkshire to the north of Barnsley it is known as Old Hards The seam is generally considered as capable of being divided into three main sections, namely, the tops, the hards or middle coal, and the bottoms Of these, the middle coal may be considered the most important, it consists very largely of durain The method of investigation in the present report has been to cut some sixteen samples from the Parkgate seam as it occurs in South Yorkshire in the exposed portion of the coalfield, ranging from a little north of Barnsley to just south of Sheffield These samples have then been fully examined, and the results of the examination are reported in detail, the determinations include approximate analysis, ultimate analysis, calorific value, melting point of ash, carbonisation assay, and ultimate and proximate analyses of the four constituents, vitrain, clarain, durain, and fusain The work has been done not only on the whole sample, but also upon the various sections into which each sample could be divided, the sample consisting in every case of a vertical prism of the coal cut from the roof to the floor When, as is sometimes the case, a certain portion of the top coal is left standing to form a roof, such portion has not been included in the sample The report gives evidence of very thorough and careful investigation, and the results should be of value to those engaged in working this particular seam, that is to say, to practically all the collieries working in the area above indicated

A NEW WARM STAGE —An electrically heated warm stage and compressor for use with high power objectives is described by Messrs J E Barnard and F V Welch in the January issue of the *Journal of the Royal Microscopical Society* The apparatus consists of a small box which encloses the heating system, the microscope stage and object holder, and also the objective and substage illuminator The box is in two parts, one of which slides off the other and permits access to the object without disturbing the microscope or its adjustments The two electrical heating elements are clamped on the under side of the stage, one on each side of the condenser, and the leads to them connected to the mains in series with a suitable variable resistance The temperature of the air inside the box is raised and the stage and compressor can therefore be maintained at a constant temperature As the compressor is a relatively large mass of metal, its temperature once raised changes little, and hence the two cover glasses between which the material is placed for observation are also maintained at a constant temperature The apparatus was designed for use in an investigation on bacteriophagic action involving observations of living bacteria for long periods, and for this purpose has proved entirely satisfactory

ULTRA VIOLET LIGHT TRANSMITTING GLASSES —An interesting paper by Starkie and Turner on the composition and properties of ultra violet light transmitting glasses has appeared in the *Journal of the Society of Glass Technology*, vol 12, No 48 An account of the development of these glasses is given, together with some analyses The limits of transmission in the ultra violet and the percentage transmission have been studied for eight commercial ultra violet glasses, and the results show a wide divergence for the different samples The ageing effect of sunlight, known as solarisation, was examined, and an exposure of several months in summer was found to reduce the transmission by more than 10 per cent in some cases Exposure to the light of a powerful arc for several hours brought about much more rapid ageing This ageing is usually accompanied by a colour change from a greenish to a brownish tint, which supports the theory of Starkie and Turner, that the dominating factor in solarisation is the conversion of ferrous to ferric oxide in the glass

THE MECHANISM OF ARCS —It seems now to be generally agreed that it is not necessary for the cathode of an arc to be hot for the discharge to pass The problem therefore arises as to how the current is maintained, if it is not primarily due to thermions from the metal, and to meet this difficulty the suggestion has been made by Prof Seeliger and by Dr Langmuir that there is an 'autoelectronic' liberation of electrons from the surface of the cathode in the high electric fields that are present in the localised region of the cathode fall in potential These fields can be of the order of a million volts per centimetre, and are ample to pull electrons out of a cold metal under appropriate conditions, such as those employed, for example, in the recently revived Lilienfeld type of X ray bulbs Unfortunately this theory requires that the current density in the cathode spot should not fall below about 1000 amperes per sq cm, whereas some arcs in gases at reduced pressure have been described by J Slepian and E J Haverstick in the January issue of the *Physical Review* in which the current density was only about one per cent of this It appears, then, that the field theory is not tenable, if its interpretation by these authors is correct and they have again directed attention in the same paper to a theory proposed by one of them (J Slepian) three years ago, which referred the maintenance of the arc not to any emission of electrons from the cathode at all, but to the thermal ionisation of a layer of gas in its immediate vicinity

RAMAN OPTICAL EFFECT —In spite of the attention that the quantised scattering of light discovered by Prof Raman has already received there are a number of points connected with it that are still obscure Perhaps the most significant of these is the difference in intensity between the Raman satellites and the corresponding infra red absorption bands and maxima of selective reflection Quartz for example, gives rise to Raman satellites equivalent to natural vibrations at 38 μ, 48 μ, and 78 μ, all of which were, until recently, unknown in the infra red spectra M Czerny has now recorded the pair at 38 μ and 78 μ as absorption bands of crystalline quartz, using a grating apparatus (*Zeitschrift fur Physik*, Feb 19), he has, however, found not the slightest trace of a band at 48 μ in this way, although there is an intense Raman satellite corresponding to this wave length The origin of these discrepancies can only be surmised at present but it may be, as the author suggests, that they arise from the fact that for a body to show the phenomena of selective reflection and absorption, the oscillators in it must have other properties than the mere possession of a definite period, whereas possibly the last condition alone suffices to produce a Raman satellite in scattered light

DETERMINATION OF TRACES OF IODINE IN VEGETABLES —McClendon and Remington, in the February number of the *Journal of the American Chemical Society*, describe a method for the estimation of small quantities of iodine in vegetables, depending on combustion in oxygen, the material being fed into a silica combustion tube by a special arrangement so as to avoid soot and tar formation Chlorides and iodides volatilise and are condensed by electrostatic precipitation Low temperature burning in open dishes requires about fifteen hours for 100 grams of dry sample, and does not lead to large losses of iodides if the ash is alkaline and the temperature never exceeds 450° Calcium lactate must be added to vegetables with an acid ash (cereals) in order to make the ash alkaline and to prevent its fusion Combustion is never complete if the ash fuses

Weather and Wireless

MR R A WATSON WATT delivered the G J Symons Memorial Lecture of the Royal Meteorological Society in the rooms of the Society on Mar 20 The lecture was illustrated by the first public demonstration, in Great Britain, of the reception by wireless picture telegraphy of current weather charts and forecasts, and also by the first public demonstration of the cathode ray direction finder Figs 1 and 2 are reproductions of the synoptic chart for 6 P M on the evening of the lecture and of a general inference and forecast based on the same data which were prepared in the Meteorological Office at the Royal Airship Works, Cardington, transmitted by the Fultograph method from the wireless station at Royal Airship Works, and received by wireless in the rooms of the Society before 8 15 P M The reproductions are from photographs of the actual Fultograms received by wireless

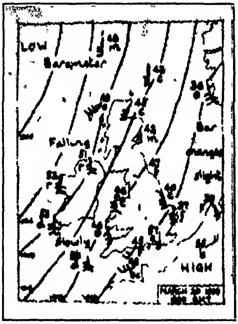

FIG 1 Synoptic chart transmitted and received by wireless on Mar 20 by the Fultograph method

Subjoined is a summary of Mr Watson Watt's lecture

WIRELESS AND WEATHER WARNINGS

Wireless communication is of vital service to the forecaster, particularly in Great Britain, because of five special facts affecting synoptic meteorology, namely, that

(1) Data from very wide areas must be utilised in the preparation of forecasts

(2) British weather comes mainly from the west

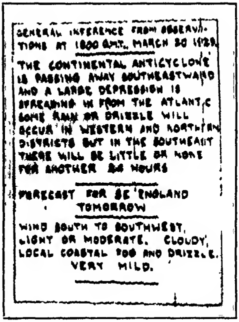
(3) The shortness of the periods for which we can at present forecast makes it imperative that the exchange of data should be extremely rapid

(4) The importance, in navigation, of meteorological data more recent than that available at the time of departure increases rapidly with the mobility, speed, and range of action of the craft concerned

(5) Aircraft require the most detailed meteorological information attainable, on account of the extreme seriousness of the results of meteorological interference with normal flying

The present state of organisation is such that the data for the whole of Great Britain is collected within an hour, sufficient data for Europe as a whole within an hour and a half, while a chart containing data for the whole northern hemisphere at 7 A M is issued before noon Data from the Atlantic shipping routes is of special importance to the British forecaster, and transmission by wireless alone can put it in his hands sufficiently quickly

The broadcasting of weather reports and forecasts is forming a public opinion which will react beneficially on the science by increasing the attention paid to meteorology in education The broadcasting of synoptic charts by picture telegraphy will enhance the value and facilitate the interpretation of the



GENERAL INFERENCE FROM OBSERVATIONS AT 1800 GMT., MARCH 20 1929.

THE CONTINENTAL ANTICYCLONE IS PASSING AWAY SOUTHEASTWARD AND A LARGE DEPRESSION IS SPREADING IN FROM THE ATLANTIC SOME RAIN OR DRIZZLE WILL OCCUR IN WESTERN AND NORTHERN DISTRICTS BUT IN THE SOUTHEAST THERE WILL BE LITTLE OR NONE FOR ANOTHER 24 HOURS

FORECAST FOR SE ENGLAND TOMORROW

WIND SOUTH TO SOUTHWEST, LIGHT OR MODERATE. CLOUDY, LOCAL COASTAL FOG AND DRIZZLE. VERY MILD.

FIG 2 —Written weather forecast transmitted and received by wireless on Mar 20 by the Fultograph method

broadcast reports An experimental period of transmission of current synoptic charts will begin at a very early date, the transmissions being made from Daventry on the Fultograph system Such transmission of charts by one of the wireless methods now available is likely to be of extreme value to the airship navigator, who must be put in possession of sufficient data for the intelligent application of the forecasts sent him The demonstration given showed the transmission and reception of current weather charts and written forecasts, and in particular the reception by wireless picture telegraphy of a synoptic chart for

6 P M of the same evening, together with a written forecast, prepared in the Meteorological Office at the Royal Airship Works, Cardington, and transmitted by wireless from Cardington

The Weather of Wireless

Wireless has a climate and a weather of its own The weakening of signals over different kinds of country, depending on time of day and season, the dependence of atmospherics on latitude, place, and time, are climatological in scope The quick period variations, erratic fading phenomena, and the like, are of the nature of weather, and atmospherics are the rainfall of wireless The history of civilisation is in the main the story of man's progress towards independence of the weather The history of wireless telegraphy is that of progress in the mitigation of these disturbing factors

The study of fading and signal variations is simplified by considering separately the energy which travels along the earth's surface and the energy which, after reaching high levels in the atmosphere, is returned to the ground level by reflection or mirage effects occurring at heights of 50 to 150 miles The ground ray is heavily absorbed, but is not subject to random variations It can therefore be depended upon to give a reliable 'service area' of limited extent around the transmitter Outside this area the ray returned from the upper levels (the 'sky wave' as it is called in America) may arrive in such a relation to the ground ray as to neutralise it, and leave no signal at all, while a slight change in the conditions aloft will cause reinforcement This gives a zone of severe fading outside the service area Still farther out the ground ray is so weak that it can never wipe out the sky wave, and so fading is actually less severe than nearer the transmitter The limited range of the ground ray means that the greater part of the world's wireless communications is carried by the sky wave It is as if stations which are out of range for direct vision communicated by lighting up a cloud layer the illumination of which is then visible at the distant receiver Most of the foreign broadcasting stations heard at night on the average broadcast receiver in Great Britian are heard by this process

Increasing sunspot activity improves the wireless mirror formed by the upper layers, and so improves long wave reception But for short waves these layers act as a cloudy prism rather than as a dirty mirror, and increased solar activity makes the layers absorb short waves more strongly, so impairing short wave wireless

Means have been developed for measuring the heights at which the turning back takes place, and the use of different wave lengths in these measurements should provide valuable data as to the constitution and properties of the atmosphere at great heights

Conditions for the travel of short waves in the upper air are often so favourable that a signal is received directly, and again after it has been once or several times round the world Moreover, it would appear that 'echoes' of this kind have been received owing to waves penetrating the upper layers, and being sent back from a reflecting surface, far beyond the moon's orbit, formed of electrons which have been emitted from the sun

Atmospherics, of which as many as three or four thousand per second can be counted in a tropical night, are found to be capable of disturbing broadcast reception at stations up to four thousand miles from the place at which they originated The average atmospheric applies to the receiving aerial an electric force a hundred thousand times as great as is needed to give a readable signal

The Effect of Weather on Wireless

Atmospherics are found to originate in thunder storms, and the predominant source of the world's supply of atmospherics at any given hour lies in a land where it is summer afternoon The strength of atmospherics radiated from thunderstorms at known distances agrees with that computed from other data about lightning, and the average atmospheric received in England is of such strength as would be radiated from a lightning flash 2000 miles away By means of visual direction finders, of the type demonstrated in operation, thunderstorms can be located by observations at stations one or two thousand miles away

The surfaces of discontinuity between cold and warm air masses, which form the principal features in the modern interpretation of the weather map, produce marked modifications in the strength of signals in the path of which they lie These discontinuities also produce errors in directional observations

The Effect of Wireless on Weather

Dr Johnson has immortalised a brief chapter "Concerning Snakes," the full text of which is 'There are no snakes to be met with throughout the whole island" Thus it is with the frequently alleged effects of broadcasting on the weather

It is to be remembered that all the rainfall of the world must be produced by evaporation, and that the average rainfall of England requires for its evaporation the expenditure of energy at the rate of a third of a million horse power per square mile, night and day, throughout the year This is the approximate power of the Barking super power station, the largest electricity generating station in Great Britain The total rate of emission of energy from all the broadcasting stations of Great Britain and Northern Ireland, in the limited periods during which they are working, is less than 55 horse power, the corresponding figure for Europe being about 400 horse power Any effect of broadcasting on rainfall would, therefore, mean the exercise of control by the expenditure of energy amounting to less than one part in a thousand million, a reaction so sensitive that it could not have escaped detection in the laboratory The scale may be represented in another way by remarking that the annual rainfall for a single tennis court, if the energy required for evaporation were purchased at a favourable rate as electrical energy, would cost about £800, while the London listener pays only ½*d* per annum, in his 10*s* licence fee, for transmitter power The expenditure on transmitter power for all the B B C stations amounts to only ½*d* per licence

Wireless and Weather Warnings

Extensions of the application of wireless telegraphy in meteorological communications may well include the transmission of three colour charts, in which the fronts are indicated in distinctive colours The detection and location of thunderstorms by wireless direction finding on atmospherics has been tested, and further experimental work is likely to lead to applications of this method in the meteorology of air routes It is possible that some of the other measurements of the effects of weather on wireless, as described, may be of use as aids to the forecaster in the identification and location of fronts It may also be possible to trace a relation between measured ionisation gradients at considerable heights and the convective processes in the troposphere

The Stereochemistry of Tellurium

By Prof T M LOWRY, F R S

NEARLY ten years ago the late Mr R H Vernon made a remarkable series of observations on the occurrence of isomerism in the alkyl derivatives of tellurium[1] The initial compound can be prepared by the direct action of metallic tellurium on methyl iodide, $Te + 2CH_3I \rightarrow Te(CH_3)_2I_2$ Silver oxide then liberates from the iodide a weak 'α' base, $TeMe_2(OH)_2$, which when dehydrated undergoes a molecular re arrangement, and is converted into a rather stronger 'β' base From this 'β' base a series of 'β' salts can be obtained, which [illegible] the same composition as the 'α' salts derived from the 'α' base. Measurements of boiling points of solutions in acetone, and of freezing points of solutions in benzene and in nitrobenzene, indicated that the two chlorides had the same normal molecular weight, but that, whilst the α dibromide and the α di iodide were also normal, the β compounds were partially polymerised thus

MOLECULAR WEIGHTS

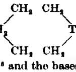
	α (Obs)	β (Obs)			Calc
Chlorides in acetone	229	226	230	223	228
Bromides in acetone	335	430	459	525	317
Bromides in nitrobenzene		400	445	370	
Iodide in benzene	401				411
Iodide in acetone		509	707		

In view of the equality of molecular weights of the chlorides, and of the methods by which the α and β salts were produced, Vernon supposed that they represented the *trans* and *cis* forms of molecules having a square configuration, like that which Werner assigned in 1893 to the isomeric platinous compounds of the type $Pt(NH_3)_2Cl_2$, thus

α Di iodide (*trans*) α Base (*trans*) Anhydrous β Base β-Di iodide (*cis*)

The thorough character of the work the simplicity of the explanation, and the obvious analogy with platinum, won for this scheme an immediate and universal acceptance, and it was a source of pleasure to me, in view of my intimate association with Vernon's earlier activities, to be able to record in December last[2] the fulfilment of Vernon's prediction in reference to the diethyl base that "If this base does not decompose when its solution is evaporated to dryness, but gives diethyltelluronium oxide, the existence of two haloid series would be highly probable" A detailed physico chemical study with Mr Gilbert[3] of Vernon's own compounds had also confirmed the equality of molecular weights of the α and β compounds, since measurements of the freezing points of aqueous solutions gave almost identical values for van't Hoff's i factor, namely, 1 1 for the α and β bases, and about 1 8 for the α and β hydroxychlorides $TeMe_2(OH)Cl$

Although, however, Vernon's experiments were impregnable, and the evidence for identity of molecular weight appeared to be ample, the writer concluded[4] that "The striking difference in colour of the α and β-dihalides shows that the isomerism of the α and β compounds must include some factor which is not expressed completely by merely putting two halogen atoms and two alkyl radicals at adjacent or at opposite corners of a square" Serious reasons for doubting the validity of the whole scheme were found for the first time, however, when further experiments showed[5] that a *cyclo* telluropentane di iodide,



prepared by Morgan, and Burgess[6] and the bases and salts derived from it, behaved in five different points like the corresponding α compounds of Vernon's series, to which he had assigned a *trans* configuration Examination of models showed that, whilst it was easy to form a strainless ring in the case of a *cis* compound, the formation of a *trans* ring involved as usual an intolerable strain which produced a corresponding strain on the theory and made it desirable to look round for possible alternatives An analysis of the facts which were then available, showed that a larger number of them could be covered by assigning to quadrivalent tellurium a tetrahedral instead of a planar configuration[7] but, in order to explain the formation of α and β isomerides, it was necessary to distort the regular tetrahedron, which is accepted universally in the case of sulphur, by making one valency different from the other three

A new series of experiments, described by Dr H D K Drew before the Chemical Society on Jan 17 (*Jour Chem Soc*, p 560, 1929), has removed the last obstacle to a complete analogy between sulphur and tellurium by showing that the changes recorded by Vernon involve an alteration of structure which goes beyond the limits of stereoisomerism This change of structure was actually observed by Vernon, who showed, while the α di iodide and potassium carbonate gave a basic salt,

$$2\ \alpha\ TeMe_2I_2 + K_2CO_3 \rightarrow I\ \ TeMe_2\ \ O\ \ TeMe_2\ \ I + 2KI + CO_2,$$

the β di iodide and potassium carbonate gave tri methyltelluronium iiodide by the wandering of a methyl group,

$$2\ \beta\ TeMe_2I_2 \rightarrow TeMe_3I + \ \ ?$$

Vernon supposed that this wandering took place under the influence of the alkali but Drew's experiments show that it had already taken place in the preparation of the β base, since the β di iodide is itself a complex salt, which can be synthesised readily from the *mono* and *tri* methyltelluronium iodides,

$$TeMe_3I + TeMeI_3 \rightarrow TeMe_3I\ \ TeMeI_3 \text{ or } [TeMe_3]^+\ [TeMeI_4]^-$$

The structure of these compounds was confirmed by a corresponding synthesis of the "β dibromide" $TeMe_3Br$, $TeMeBr_3$, and of mixed halides of the composition $TeMe_3Br$, $TeMeI_3$ and $TeMe_3I$, $TeMeBr_3$

The simple salts from which the more complex β compounds were synthesised are obviously derivatives of trimethyltelluronium hydroxide, $TeMe_3OH$, and of the monomethyl compound Me TeO OH, which Drew describes as telluracetic acid He there

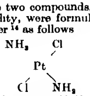
fore assigned to the β base the structure of an *anhydride*, TeMe$_2$O TeMeO Since, however, the monomethyl compound can be shown to have an acid rather than a basic reaction,[8] it is clear that the mixture of *mono* and *tri* methyl hydroxides should form a *salt* $[TeMe_3]^+$ [Mo TeO O] The correctness of this alternative view can be established from measurements of conductivity,[8] which show that the 'β base' gives a curious series of values ranging from $\Lambda^{25}_{32} = 31$ to $\Lambda^{25}_{512} = 37$ These can be explained by assigning to the cation $[TeMe_3]^+$ a mobility of 50, as in the case of $[NMe_4]^+$, and to the anion CH_3 TeO O a mobility of 30, as in the case of the acetate ion CH_3 CO O, giving a limiting conductivity of 80 for the salt, or 40 for each atom of tellurium, in close agreement with the data recorded above

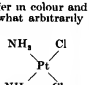
It is important to point out that whilst the *stereoisomerism* of Vernon's theory has been disproved, the *isomerism* indicated by his experiments may still be valid for some of the compounds of this series In particular crystallographic evidence suggests that the α di iodide is itself a complex compound, with a structure that is very similar to that of the β di iodide, there are therefore clear indications that the α dihalides may form complex molecules of the type $[TeMe_2I]^+$ $[TeMe_2I_3]$ which would be isomeric with $[TeMe_3]^+$ $[TeMeI_4]$, although they are evidently more readily dissociated into molecules or ions containing only a single atom of tellurium

The abrupt disappearance of the only evidence which justified the representation of quadrivalent tellurium by a planar model at once raises the question whether the analogous configurations for quadrivalent platinum and palladium are likely to survive In a matter of this kind, prediction is dangerous, but it can at least be said that the planar formulæ for palladium and platinum are supported by a greater variety of evidence and are therefore much less likely to collapse under a single blow The evidence cited by Werner in 1893[9] corresponds closely with that obtained by Vernon So long ago as 1828, Magnus,[10] by the action of ammonia on platinous chloride, obtained a compound which is still known as *Magnus' green salt* This has the empirical composition $PtCl_2$ $2NH_3$ but behaves as a complex salt of the formula, $[Pt\ 4NH_3]^{++}$ $PtCl_4$ When boiled with ammonia it is converted into *Reiset's salt*,[3] $[Pt\ 4NH_3]^{++}Cl_2^-$, which on heating to 250°[11], or on boiling with concentrated hydrochloric acid,[12] is converted into two isomeric forms of the non valent diammine $[2NH_3\ PtCl_2]$ These two isomers, which can be prepared more readily by the action of ammonia on ammonium platino chloride,[13] $(NH_4)_2PtCl_4$, are distinguished, for no very obvious reason, as platosammine chloride and platosemidiammine chloride

The two compounds, which differ in colour and in solubility, were formulated somewhat arbitrarily by Werner[14] as follows



Platosammine chloride
(sulphur yellow)
β or *trans*



Platosemidiammine chloride
(orange yellow),
α or *cis*

On account of their limited solubility, their molecular

weights were not determined precisely until 1926, when Reihlen and Nestle[15] made a series of observations on the vapour pressures of solutions in liquid ammonia These showed that the *cis* compound had a normal molecular weight, whilst that of the *trans* compound was twice as great On the other hand, Grunberg[16] has obtained normal values for solutions in acetone of both forms of the thiocyanate, $[2NH_3\ Pt(CNS)_2]$, Hantzsch[17] has obtained normal molecular weights for solutions in phenol of both forms of the dipyridyl compound $[2C_5H_5N,\ PtCl_2]$, and Kraus and Brodkorb[18] have obtained normal values for the two forms of $[2C_5H_5N\ PdCl_2]$ and $[2EtNH_2\ PdCl_2]$, as well as for one form of $[2NH_3\ PdCl_2]$, the other being hydrolysed too readily to permit of accurate measurements

Up to this point the story is an almost exact duplicate of the recent observations on tellurium, since the mere multiplication of examples of α and β compounds does not rule out the possibility of an alternative explanation of the supposed isomerism in either case, and the repeated determinations of molecular weights have again provided conflicting evidence It is also open to question whether the occurrence of the same isomerism in tetrammines of the type $[2C_5H_5N\ Pt\ 2NH_3]Cl_2$, might not stand or fall with that of the diammines Fortunately, however, physical evidence is now available which appears to be decisive on the point at issue Thus crystallographic observations have shown that the double cyanides, $K_2[Zn\ 4CN]$, $K_2[Cd\ 4CN]$, $K_2[Hg\ 4CN]$, crystallise in the *cubic* system, and X ray analysis[19] confirms the obvious deduction that the anion has a tetrahedral configuration, such as has already been found in the molecules of $[SnI_4]$, although the ion $[SnCl_6]$ has an octahedral configuration On the other hand, the two pallado chlorides, $K_2[PdCl_4]$ and $Am_2[PdCl_4]$, and the platinochloride $K_2[PtCl_4]$ all crystallise in the *tetragonal* system, and X ray analysis[20] confirms the deduction that the anion has the same symmetry as the crystal and must be represented with the four halogens at the corner of a square of which the metal occupies the centre The planar configuration which Werner assigned to this group of compounds thirty five years ago is therefore now established by a process of mensuration, which does not encourage any hope of its disestablishment by less direct chemical methods

University and Educational Intelligence

London —Dr Harold Raistrick has been appointed as from Aug 1 to the University chair of biochemistry tenable at the London School of Hygiene and Tropical Medicine, where he will also hold the position of Director of the Division of Biochemistry and Chemistry as applied to Hygiene Dr Raistrick is a graduate of Leeds and Cambridge From 1915 until 1920 he was engaged on research work on the biochemistry of micro organisms for the Medical Research Committee in Sir Frederick Hopkins's laboratory at Cambridge, and since 1921 he has been on the research staff of Messrs Nobel's Explosives Company, Ayrshire, where he organised and equipped a new Biochemical Research Department

The National Union of Teachers held its annual conference this year at Llandudno on Mar 30 The

presidential address, delivered by Mr C W Cowen, of Sheffield, emphasised the increasing, and increasingly necessary, solidarity of the teaching profession and the broadening of the basis of the Union since 1888 when the word 'elementary' was eliminated from its title Referring to the Board of Education's pamphlet on "The New Prospect in Education" and the reorganisations designed to provide advanced instruction for all pupils of secondary school age, the president, while regretting that it has not been decided to enforce throughout England the raising of the age limit of compulsory attendance, pointed out that such reorganisations involve risks of hardship in individual cases and appealed to the Board that local education authorities should not be compelled to proceed immediately with far reaching schemes but invited to put them into operation cautiously and by stages as vacancies arise through retirement or other causes Turning to the relationship between education and industry, and to the gap left by the decay of the apprenticeship system, he expressed the opinion that as an effective training must be based upon an adequate general education, the raising of the school leaving age to at least fifteen years is an essential preliminary to advance He lamented the destruction, attributed to the opposition of small scale employers, of the powerful movement towards day continuation schools He closed with an appeal to teachers to take an even greater part than they do already in all social movements which tend to the uplift of the masses of England

FROM the Universities Bureau of the British Empire we have received a pamphlet (pp 36, price 1s) containing lists of students from other countries in the universities and university colleges of Great Britain and Ireland in the current session The names of the students are grouped, separately for each institution, under the names of the countries to which they belong, and there is a table showing the total number of students from each of the countries named The grand total of these numbers is 5170 The countries contributing most to this total are India and Burma 1575, South Africa and Rhodesia 574, United States of America 556, Egypt 382, Australia and New Zealand 336, Canada and Newfoundland 203, Germany 157, West Indies 128, Ceylon 121, China 93 Of the Indian students more than half are in the London colleges, and of the remainder Oxford and Cambridge have 181 the modern English provincial universities 288, Edinburgh 133, and Glasgow 99 Of the 574 South Africans, 222 are in the London colleges (123 in the medical schools) 163 at Oxford and Cambridge, 100 at Edinburgh Oxford has 168 students from the United States, including 96 Rhodes Scholars, Cambridge 64, London 136, and Edinburgh 127 The Egyptian students are chiefly in the modern English provincial universities (162), especially Birmingham (55), in London (131), and also in Edinburgh (55) Australians and New Zealanders congregate chiefly in Oxford and Cambridge (157), London medical schools (64), and Edinburgh (37), Canadians in the London colleges (77), Oxford and Cambridge (74), and Edinburgh (35) German students have been coming to England in rapidly increasing numbers in the past four years, they are chiefly in London (94), especially the School of Economics (40), and the modern English provincial universities A comparison with similar pamphlets published two years and four years ago discloses some interesting increases grand totals—4385, 4596, 5170, India, Burma, and Ceylon, 1199, 1361, 1696, Germany, 34, 93, 157, and decreases—South Africa, 747, 624, 574, Siam, 79 62, 37

Calendar of Patent Records

April 6, 1852—It was Samuel Fox who introduced the light steel frame for umbrellas and parasols His patent for constructing the ribs and stretchers of steel formed into hollow trough like shapes was granted on April 6, 1852, and the frames were put on the market under the well known 'paragon' mark

April 9, 1788—The first beater thrashing machine was patented on April 9, 1788, by Andrew Meikle, who was led to the invention by making experiments with a machine of a different type which did not work satisfactorily John Rastrick, the engineer, was also trying to solve the problem at the same time, and says himself that he had made machines on Meikle's plan about ten years before the date of the patent, but though there is evidence that Meikle's rights were contested and that he obtained little benefit from his patent, nothing has so far come to light to support Rastrick's claim to be the real inventor

April 10, 1790—The first federal Patents Act of the United States was passed on April 10, 1790, and the first grant under it was made to Samuel Hopkins in the following July Many patents had, however, been issued previously, by extension of English patents by the Crown to include one or more of the colonies, directly by the colonial authorities, and, after the Declaration of Independence, by Acts of the various State legislatures, especially Maryland, Connecticut, Massachusetts and Pennsylvania

April 10, 1811—In the first days of the railway locomotive, it was widely held in spite of evidence to the contrary—that the adhesion of smooth wheels on the rails would not be sufficient to enable heavy loads to be drawn along the railway, and Blenkinsop's rack locomotive was designed to overcome this objection This was patented on April 10, 1811, and was introduced on the tramline of Middleton colliery, near Leeds

April 11, 1807—The modern method of igniting the powder charge in all fire arms dates from the invention of the percussion lock by the Rev Alexander John Forsyth, the patent for which is dated April 11, 1807 Forsyth used as his detonating powder a mixture of potassium chlorate sulphur, and charcoal, but the specification is drawn in wide terms to include all percussion systems, and the patent was held to be good after a strenuous fight in the courts The British government was, however, slow to adopt the new method, and Forsyth received no benefit from his patent, though his heirs were afterwards given a government grant of £1000

April 13, 1847—Theodore Boehm's improvements in the flute, which consisted mainly in the provision of a cylindrical instead of a tapering bore, and the adoption of a system of rings and levers in combination with the keys, whereby the fingers were given much easier control, received a Bavarian patent for five years on April 13, 1847 The introduction of the new flute raised a great controversy both as to the merits of the new construction and to Boehm's claims to be the inventor, but its use soon became general

April 13, 1869—George Westinghouse's first patent for a continuous air brake for railway trains was granted in the United States on April 13, 1869 The idea did not originate with Westinghouse, but his construction embodying the three way control cock and automatic valves in the connecting tubes, which ensured that the system would still continue to work if part of the train became disconnected, was the first practical system, and was immediately taken up It was greatly improved in the following years, and by 1874 had been fitted to more than 2000 locomotives and 7000 coaches

Geneva

Society of Physics and Natural History, Dec 20 —**R Bach** and **A Schidlof** The allotropic states of iron It is generally admitted, from earlier researches, that iron has four allotropic varieties, α, β, γ, δ, and is characterised by the same crystal network for α, β, δ (centred cube), and another face centred cube for γ The authors find confirmation of these views from the study of the variations of the constant of the crystal network in the neighbourhood of the transformation points of the different varieties —**L Reverdin** Faunistic study of the station of Sumpf (Zoug), the Bronze Age (2) The author completes the results of the excavations of 1926 by those of the years 1927 and 1928, obtained at two new places The numerical proportions of the different species vary from one field to the other, but the sheep preponderates Taken as a whole, the descending order is sheep, ox, dog, pig, horse J Favre has determined the molluscs Those of the archæological layer are characteristic of aquatic deposits without exception The presence of *Valvata piscinalis*, var *antiqua*,

shows that it was a lake and not a marsh.—F. Battelli: The relation between the voltage and the duration of the stimulation in the production of convulsions. Continuous current and alternating current (frequency, 45), with the voltage rising from 10 to 86 volts, were applied to the frog. For the lower voltages the action of the alternating current is much more prolonged, but the durations tend to equality starting from 45 volts.

ROME

Royal National Academy of the Lincei, Dec. 2.—**Gino Fano**: S. Lie's representation of the linear element of the plane on dotted space.—**L. Cambi**: Univalent iron, cobalt, and nickel, and nitrosothio salts: reply to W. Manchot.—**A. Palatini**: Constant tensors associated with binary and ternary varieties.—**Maria Pastori**: Noteworthy identities relating to derived tensors.—**C. Burali-Forti**: A question concerning elastic films.—**E. Čech**: The asymptotic correspondence between two surfaces.—**G. Vranceanu**: The equations of the problem of two bodies of variable mass. Levi Civitá has recently considered the problem of the motion of a body, the mass of which varies as the result of the fall of meteorites on to it (astronomical case) and arrives at the conclusion that $\frac{d}{dt}(mv) = F$ should be taken as the fundamental law. The equations of the problem of two bodies of variable masses, which is of astronomical interest, are now considered.—**E. Guglno**: A new interpretation of Gauss's principle of minimum contraction.—**B. Finzi**: The singularity of dynamic actions in the problem of the plane strip.—**R. Serini**: Symmetrical deformations of an elastic strip.—**D. Graffi**: The theory of the transmission of heat by convection.—**Stefano Lodovico Straneo**: Application of the functional method to the study of the cooling of a bar.—**A. Occhialini**: The effect of resistance on a spark spectrum. A method is described which allows of the classification of the lines emitted by an element, and is based on their behaviour when a resistance is inserted in the discharge circuit. Use is made of low voltage spark spectra, and, if the resistance is sufficiently high, the spectrum lacks certain lines, whereas if the resistance is diminished those lines appear adherent to the cold electrode in groups at definite values of the resistance.—**M. Kahanovicz**: Elastic constants in relation to the periodic system of the elements. Elasticities of form, volume, and tension are progressive functions of the atomic number. The relationships are simple proportionalities, and the product of the modulus with the atomic number constitutes a constant characteristic of the group. Various conclusions are drawn concerning the mutual relationships between the different deformations.—**G. Bargellini** and **Lydia Monti**: 2 : 5 Dichlorophenetidine. The dichlorophenetidine obtained by Reverdin and During by treating phenacetin, in acetic acid solution, with nascent chlorine and hydrolysing the resulting dichlorophenacetin, is the 2 : 5 compound.—**R. Altschul**: A new procedure for staining glial cells. Weigert's method for revealing the marginal glia, the fibrous glia, and their relations to the vessels may be greatly simplified and rendered more certain in its results.—**C. Ruiz**: The fauna of the Jurassic volcanic tufas of Roccapalumba, Sicily.—**Constantino Gorini**: Thermobiosis and microbic dissociation. By thermobiotic culture is meant, not adaptation of organisms to high temperatures, but treatment to ascertain if some of the cells are more or less thermophile. This is done by subjecting the cultures, suddenly and as soon as they are inoculated, to temperatures ranging from 50° to 70°, the daily re-inoculation of each culture being made at its own special temperature. In this way a mesophile species of the *Subtilis* group has been dissociated into a strain showing transitory thermo-tolerance and another exhibiting lasting thermo-tolerance.—**G. Testi Dragone**: Fluorescence of vegetable juices in filtered ultra-violet rays. The experiments on the effects of the rays from a Hanau lamp, after passage through a uviol filter, on the latex from plants of various families, have now been extended to the resinous substances of a number of Coniferæ and to the essential oils of the pericarp of various *Citrus* species. The resins exhibit fluorescence, which is usually blue, but sometimes greenish or brownish. These substances, then, protect the parts of the organism producing them from harmful, invisible radiations by converting these latter into harmless radiations of greater wave-length. Similar results are obtained with the oleiferous glands of *Citrus*.—**N. A. Barbieri**: Physiological culture: results and applications. The author has previously shown that it is possible to separate, from vegetable tissues, the soluble and insoluble salts existing preformed therein. These salts as a whole, constitute the physiological fertiliser, which is the saline nutriment most suitable to, and most readily assimilable by, a plant. Various crops, when fertilised on these lines, give favourable yields in comparison with similar crops to which the fertilisers commonly used are applied.—**V. Bambacioni**: Contribution to the embryology of *Lilium candidum* L. Various observations are recorded of interest not only as regards the development of the feminile gametophyte which, perfectly identical with that of *Fritillaria persica*, follows the *Euphorbia dulcis* type and explains in the simplest manner the increase in the number of chromosomes in the nuclei of the chalazal region, but also on account of a number of anomalies, some not previously described.

Diary of Societies

FRIDAY April 5

INSTITUTE OF BRITISH FOUNDRYMEN (Lancashire Branch) (Annual Meeting) (at College of Technology Manchester) at 4 —J Yates Foundry Organisation

ROYAL SANITARY INSTITUTE (at Council House Birmingham) at 5 30 —H. H Humphries Some Drainage Problems in Birmingham

INSTITUTE OF TRANSPORT (Manchester Liverpool and District Section) (at Manchester), at 6 30 —D R Lamb Sidelights on the Transport Problem

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section) at 7 —E. W Hill Some Technical Considerations concerning Power Factor in Relation to Tariffs

JUNIOR INSTITUTION OF ENGINEERS (Informal Meeting), at 7 30 - Technical Film showing the Production of Graham Paige Cars in America.

INSTITUTION OF MECHANICAL ENGINEERS (Midland Graduates Section) (at Chamber of Commerce Birmingham) at 7 30 —Wing Comm T R Cave Brown Cave Aircraft Engineering in its Relation to Mechanical Engineering (Annual Lecture).

SATURDAY, April 6

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (Yorkshire District) (at Town Hall Leeds), at 2.30 —Resumed Discussion on the Address by W J Hadfield on The Local Government Bill and the Municipal Engineer with Particular Reference to the Compensation Clauses.

HULL ASSOCIATION OF ENGINEERS (at Technical College Hull), at 7 15 —H E Copp The Carbonisation of Coal

MONDAY April 8

ROYAL SOCIETY OF MEDICINE (War Section) (Annual General Meeting) at 4 30 —Col J C Kennedy, Surg Rear Adml E T Meagher, Squad Leader M I Burton Discussion on Functional Diseases of the Nervous System.

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4.30 —Lt Col L M Davies The Philosophic Basis of Modernism.

ROYAL SOCIETY OF MEDICINE (Orthopædics Section), at 5 —W H Ogilvie A Review of Recent Work on Bone Tumours.—R. Watson Jones Wrist Dislocation with Associated Nerve Lesions.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 —General Meeting

SOCIETY OF ENGINEERS (at Geological Society) at 6 —G H Gardner Notes on the Inspection of Public Works.

INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Centre) (Annual General Meeting) (at Armstrong College, Newcastle upon Tyne), at 7 —B L. Goodlet The Testing of Porcelain Insulators.

SOCIETY OF CHEMICAL INDUSTRY (Yorkshire Section) (Annual General Meeting) (at Hotel Metropole, Leeds) at 7 15 —Dr E G Ritchie The Storage of Steam in Industrial Plants

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8 —Major General Sir Fabian Ware The Work of the Imperial War Graves Commission

SURVEYORS INSTITUTION at 8.—B W Adkin The Education of a Young Surveyor

TUESDAY, April 9

SOCIETY FOR THE STUDY OF INEBRIETY (at 11 Chandos Street, W), at 4 —Dr J D Rolleston and others Discussion on Alcohol in Therapeutics

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5 30 —Dr L. Dudley Stamp The Oil and Gas Fields of Burma.

ZOOLOGICAL SOCIETY OF LONDON at 5.30 —S. R Douglas Further Results of Dr Wilfrid Ashley's Experiment on marking Woodcocks breeding in the West of Ireland —J W Winterbottom Studies in Sexual Phenomena—Continual Display in Birds —W S. Bristowe (a) The Mating Habits of Spiders, with Special Reference to the Problems surrounding Sex Dimorphism (b) (1) The Spiders of the Scilly Islands (2) The Spiders of Lundy Island (3) A Contribution to the Knowledge of the Spiders of the Channel Islands —C J Conolly A New Copepod Parasite representing a New Genus and its Larval Development

INSTITUTION OF CIVIL ENGINEERS, at 6.—H Hall The New Piccadilly Circus Station

LONDON NATURAL HISTORY SOCIETY (at Winchester House Old Broad Street), at 6 30 —J E S Dallas Summer in Switzerland

INSTITUTE OF MARINE ENGINEERS at 6.30 —W E Woodeson jun and J S Gander The Relative Merits of Pulverised Fuel and Mechanical Stoking and their Application for Marine Purposes.

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole Leeds) at 7 —Annual General Meeting

INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre) (Annual General Meeting) (at Engineers Club Manchester) at 7 —Hon Sir Charles A Parsons and J Rosen Direct Generation of Alternating Current at High Voltages —J A Kuyser Recent Developments in Turbo Generators

INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Section) (Annual General Meeting) (at Royal Technical College Glasgow), at 7 —E B Wedmore Dr W B Whitney and C E R Bruce An Introduction to Researches on Circuit Breaking

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN at 7 —S H Horgan Bringing Photography to the Printing Press.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Middlesbrough Branch) at 7 30

INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND (at 39 Elmbank Crescent Glasgow) at 7 30 —Dr Ing F Sass Experiences with and Investigations on Double acting Airless injection Diesel Engines

INSTITUTION OF AUTOMOBILE ENGINEERS (at Royal Society of Arts) at 7 45 —H S Rowell and C G Williams Automatic Spark Advance

ROYAL SOCIETY OF MEDICINE (Psychiatry Section) (jointly with British Psychological Society Medical Section), at 8 —Dr E Jones Dr H Yellowlees Dr R D Gillespie and others Discussion on The Role of Anxiety in the Psychoses and Psycho neuroses

TELEVISION SOCIETY (at Engineers' Club Coventry Street) at 8 —J C Rennie Some Notes on Exploring

WEDNESDAY April 10

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section) at 6 —T L Eckersley Short Waves

MALACOLOGICAL SOCIETY OF LONDON (in Zoological Department, University College) at 6

ROYAL SOCIETY OF ARTS at 8 —G H Nash Some Modern Aspects of Electrical Communication

ELECTROPLATERS AND DEPOSITORS TECHNICAL SOCIETY (at Northampton Polytechnic Institute) at 8 30 —B Clark Effect of Organic Addition Agents in the Electro-deposition of Copper

THURSDAY April 11

TEXTILE INSTITUTE (at Midland Hotel Bradford) at 7 30 —H T Tizard Science and the New Industrial Revolution (Mather Lecture)

INSTITUTION OF ELECTRICAL ENGINEERS at 6 —B L Goodlet The Testing of Porcelain Insulators

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6 30.—M Lapresle Wind Tunnel Methods of the Eiffel Laboratory

INSTITUTE OF METALS (London Local Section) (Annual General Meeting) (at 83 Pall Mall) at 7 30 —Dr Hankins and others Discussion on Hardness Testing

ROYAL SOCIETY OF MEDICINE (Neurology Section) at 8.30 —Discussion on Disseminated Encephalo-myelitis

NELSON TEXTILE SOCIETY (at Nelson).—F Hughes Sley Construction and Traverse of Shuttle

FRIDAY, April 12

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30 —A. T Cooper Recent Electrical Developments in India

ROYAL ASTRONOMICAL SOCIETY at 5 —L Rosenhead The Annual Variation of Latitude —E A. Kreiken On the Dwarf Nature of the Spectroscopic Binaries —H Horrocks The Longitude of the Royal Observatory Cape of Good Hope, from Wireless Signals, Oct.-Nov 1926 —S A Mitchell Atlas Stellarum Variabilium Series VII

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute Newcastle upon Tyne), at 6

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (Annual General Meeting) (at Engineers Club, Manchester) at 7 —T R. Woolaston Suggestions in Steam Raising

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7 —F E F Durham Pumping Plant

GEOLOGISTS ASSOCIATION (at University College), at 7 30 —E. J Wayland The Later Geological History of the Equatorial Lakes in Uganda

OIL AND COLOUR CHEMISTS ASSOCIATION (Manchester Section) (at Milton Hall, Manchester) at 7 30 —Annual General Meeting

SOCIETY OF CHEMICAL INDUSTRY (Birmingham and Midland Section) (jointly with Chemical Engineering Group) (at Engineers Club, Birmingham) —Dr C M Walter The Design and Operation of Gas Heated Furnaces.

SATURDAY April 13

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (jointly with Yorkshire and North Western Districts) (in College of Technology, Manchester), at 2 30 —W J Hadfield The Local Government Bill, with Particular Reference to the Road Clauses.

Co-education.

SCIENCE does not give a clear lead on the question of co education The physiological and psychological differences between the sexes are not 'significant enough to determine whether the sexes should preferably be educated together or apart When in 1922 the Consultative Committee of the Board of Education was preparing its valuable report on Differentiation of the Curriculum for Boys and Girls respectively in Secondary Schools it wisely consulted a distinguished medical man the late Dr J G Adami on the anatomical and physiological differences between the sexes Dr Adami classified those differences under four headings—(*a*) rate of growth (*b*) date of adolescence (*c*) anatomical age and (*d*) after puberty the composition of the blood—and gave the Committee all the information available on the interrelationship of the internal secretions and the essential and secondary organs of sex for as he said obviously it has a profound bearing upon the problem before the Committee

The lower proportion of red blood corpuscles in women has been established by several workers Dr Adami discussed at some length recent work on the calcium metabolism of the body referring especially to Blair Bell s conclusion that with the onset of puberty the calcium metabolism in the female becomes unstable whereas in the male it remains comparatively constant The committee observes that at that time Blair Bell s views had not been generally accepted by physiologists but it appeared possible that the greater nervous excitability of the feminine sex might be ascribed to a deficiency in calcium If the Committee showed a disposition to study its problem in the dry light of science its recommendations stressed the need for further inquiries rather than the value of results already attained

It must be remembered that the Consultative Committee was not concerned directly with the question of co education Evidence on this question was however received and a digest is given in an appendix The questions considered refer to the relations between boys and girls in mixed schools—whether, for example, boys tend to take a preponderating part in the social life of the school—the danger of overpressing girls and not pushing boys forward sufficiently, the relative failure to meet the individual needs of some girls, and, finally, staffing difficulties These last appear to be the most serious, for the position under which mixed schools are, with some exceptions, under the control

of head masters, does not appear to offer a final solution Women's education has already suffered too much from 'man made' curricula, and a state of things in which all the responsible appointments in secondary education are held by men would not be acceptable to women under present social and political conditions

Originally, in Great Britain, as in the United States, the establishment of mixed secondary schools took place without much premeditation The geographical distribution of these schools in England is curious Buckinghamshire, Derby shire, Durham, Gloucestershire, Hampshire, Lanca shire, Middlesex, Suffolk, Wiltshire, and the West Riding appear to like mixed schools, Kent, London, Northumberland, Staffordshire, Surrey, and Warwickshire appear not to like them Lancashire has thirty three mixed schools and thirty eight boys' schools under the county authority, London has three mixed schools compared to forty boys' schools Mr R F Cholmeley, in his chapter on the boys' day school, contributed to "The Schools of England," edited by Prof Dover Wilson, remarks that the origin of most of these mixed schools is due to convenience, including financial convenience, but he adds that "the interesting thing about them is the growth of a belief in them on educational grounds, and the remarkable success of their work" He regards the growth of the mixed school as one of the most striking developments in day school education The proportion of mixed schools to boys' schools is almost exactly seven to eight, and the number of boys educated therein as two to five

If the growth of the mixed school has been without premeditation, the same may be said of the growth of the girls' secondary school and college The pioneers of women's education saw the nakedness of the land and established new schools and colleges for girls and women, making, at the same time, a reasonable claim to a small share of educational endowments The University of London was an early convert to co *examination*, admitting women to all examinations in 1878, with the significant reservation that "no female graduate of the said University shall be a member of Convocation of the said University, unless and until such Convocation shall have passed a resolution that female graduates be admitted to Convocation" Here we see obtruding the old and difficult question of control, a question of much controversy also at Oxford and Cambridge In London this question has advanced a distinct stage under the new statutes which grant official membership of the Senate to the heads of several women's colleges, an 'ability' accorded to women which will be generally approved, as it seems desirable to ensure the inclusion of women on the governing bodies of universities

In the British universities generally, co education prevails and is unavoidable in the case of subjects studied by a small number of students Oxford, Cambridge, and London, partly owing to their collegiate organisation, present some special problems

The question of medical co education in London has been widely discussed in consequence of the decision of several medical schools in future to exclude women students, a reversal of the policy adopted during the War The usefulness of the Report of the Committee of the Senate of the University of London on this subject is, however, reduced, because it was not found possible to state specifically the reasons which led the medical schools in question to this decision, nor is there any report by the Faculty of Medicine, the advice of which we should have expected the Senate to seek on constitutional grounds The committee states "We are unable to see any valid argument on the merits against the provision of co education in medicine The pre possession of the University is in favour of such co education" Seeing that a large majority of the existing colleges of the University are unisexual, and that seven medical schools have recently expressed a preference for uni sexual education, it is difficult to see on what evidence this 'prepossession' is based Statistics appended to the Report indicate that there is at present no difficulty in women undergraduates obtaining medical education, for whereas in 1920–21 the London School of Medicine for Women had 447 full time students, that number had fallen in 1926–27 to 297 The throwing open of the other medical schools to a 'quota' of women would tend to reduce the success and efficiency of this well organised school for women Apart from this, is not the 'quota' system inherently objectionable? The University would do well to ensure that all special courses, especially those by research workers at the spearhead of knowledge, should be equally available for men and women At the moment, no further action on the part of the University appears to be demanded

Since the publication of the University of London Report, an important opinion on the question of medical co education has been pronounced by Dr Louisa Garrett Anderson, who, at a meeting held at the London School of Medicine for Women on Mar 21, said that a medical school

for women alone had enormous advantages over a co educational school Where women held the professorial chairs, she added, women learned to trust women, but where there was co education it had been found that the most important work was done by men As the Senate Committee, though in its nature a lay committee, did not attempt to quote expert opinions for and against medical co education, this professional opinion by a leading woman doctor comes at a convenient moment and should carry great weight

The general tendency of co education is towards creating large institutions Co educational secondary schools of 5000 pupils are not uncommon in the larger American cities Co-education also facilitates a preponderance of one sex or the other in the teaching staff, whereas with separate schools there is a natural tendency towards an approximate equality In some of our co educational colleges, women do not appear to have obtained a fair proportion of the staff appointments Nor can co education offer much encouragement to specialisation on sex lines which may be desirable in certain subjects, *e g* medicine In higher education, which demands consecration and dedication, the presence of the other sex may act as a distraction Frank R Arnold, in an article "The Mating Season of Co education" (*Scribner's Magazine*, June 1926), refers to "co educational calf love," and argues that the finest type of woman is not likely to be produced by co-educational institutions Such women "need years of meditative acquisition, mental brooding as well as physical, and the fault of co education is that it awakens the mating mother instinct too early"

The Planetesimal Hypothesis

The Two Solar Families the Sun's Children By Prof Thomas Chrowder Chamberlin (University of Chicago Science Series) Pp xxii + 311 (Chicago University of Chicago Press, London Cambridge University Press, 1928) 12*s* 6*d* net

THIS book, which appeared on the author's eighty fifth birthday, and less than two months before his lamented death, is a summary of the well known planetesimal hypothesis of the origin of the solar system which, with the collaboration of Prof F R Moulton, he developed during the last thirty years While the greater part of the book is a restatement of previously published results, some new material is included, and the whole forms a compact and useful account of a hypothesis which, whatever may be its ultimate fate, must take high rank among the generalisations which have stimulated and elucidated geophysical research during this century

The "two solar families" are, in broad terms, the planets and the comets The former class includes the major and minor planets and their satellites, and the latter the chondrulites, comets, and meteorites In "the grey beginning of years," a star passed near the sun, and by tidal action, aided by propulsive forces in the sunspot zones, drew forth a succession of 'bolts' from the near and far sides of the sun These bolts rapidly cooled and were largely disintegrated into a multitude of 'planetesimals' which, in the course of long ages, were gradually reabsorbed by the residual nuclei of the bolts, forming the planets The cometary family owed little, if anything, to the passing star It arose from material ejected from the sun in the manner of the eruptive prominences which are even now frequently observed The hypothesis is extended in an ingenious way, without excess of purely *ad hoc* assumptions, to explain many details of the present solar system Prof Chamberlin's account is not distinguished by marked clearness of expression, but it is in the main free from ambiguity, and the meaning is rarely obscure to the careful reader A bountiful provision of good diagrams and illustrations, and excellent productive work on the part of the publishers, make up a worthy conclusion to the author's long series of contributions to geology and allied sciences

The publication of the book has seemed to Prof Moulton a fitting occasion to direct attention to certain matters connected with the planetesimal hypothesis and its reception among astronomers He has accordingly issued a pamphlet entitled "The Planetesimal Hypothesis," in which several important points are raised It is made up of two distinct parts, which may be described succinctly as constructive and destructive They are not entirely unrelated, for the instruments forged in the former are used as weapons in the latter, and in fact were clearly designed for that end, but the division is nevertheless a convenient one

In the constructive part a sharp line is drawn between hypotheses of the Laplace type and those of the planetesimal type "The gap between these different genera of intellectual constructions is as profound as that between different genera of living organisms, and as difficult to bridge" The characteristics of the genera are described by examples instead of specific statements, but it is clear that the typical feature of the former is the idea that the evolution of each cosmic mass is free from extraneous influences and consequently can be traced out rigorously

from a few fundamental principles in a statement of great simplicity If intra atomic sources of energy are ignored, these hypotheses require a cosmic time scale of tens of millions of years Hypotheses of the planetesimal type, on the other hand, regard the stars as mutually related objects, the evolution of each depending in part upon the others The simplicity of the former type does not exist, so that some parts of the planetesimal hypothesis may be accepted and others rejected The time scale required here is of the order of thousands of millions of years

Later in the pamphlet another classification is advanced which distinguishes hypotheses which are expressible in formulæ from those which are not Prof Moulton well explains the character of a 'formula' or 'law of Nature,' and although he does not actually state that this classification is a restatement of the former one, it may fairly be inferred that that is so The Laplacian theory and the Genesis account of creation are cited as examples of hypotheses expressible by simple formulæ, and the planetesimal hypothesis as an example of the other kind

So much for the constructive side of the pamphlet, now for the destructive side This originates in the relations between the planetesimal hypothesis and the views of Sir James Jeans and Dr Harold Jeffreys on the origin of the solar system, which are mainly contained in ' Problems of Cosmogony and Stellar Dynamics " (1919) of the former and " The Earth " (1924) of the latter The theories of Jeans and Jeffreys both invoke a passing star to produce the planets from the sun by tidal action, but the conditions of the process and the subsequent developments differ in the two theories, as does each of them from the planetesimal hypothesis

Prof Moulton first protests against the frequent ascription of the assumption of a passing star, and the proof of the invalidity of Laplace's hypothesis, to Jeans instead of to the prior work of Chamberlin and himself Further, although the time scale of cosmic processes has lately been greatly extended through the discovery that intra atomic energy might be available for stellar radiation, no adequate acknowledgment has been made of the fact that this possibility was urged by Chamberlin nearly thirty years ago

This, however, is not all Prof Moulton goes on to denounce the methods of Jeans and Jeffreys in claiming credit by implication for Chamberlin's work He complains that these writers give the impression that the idea of a passing star and allied conceptions are mainly due to British workers, and that they do not fairly indicate the date of birth of the planetesimal hypothesis, so that priority is likely to be wrongly assigned He gives a history of the development of that hypothesis and compares it with the later work of Jeans and Jeffreys, concluding that the 'tidal theory' of these writers is identical in every essential concept with the planetesimal hypothesis and that the former is an abortive attempt to put the latter into a formula

From the point of view of scientific history and general principles, Prof Moulton's pamphlet has much importance and some justification There seems to be no doubt that due acknowledgment has not generally been given to the work of Prof Chamberlin and himself with respect to the assumption of a passing star, the criticism of Laplace's hypothesis, and the realisation of the factors determining the cosmic time scale The planetesimal hypothesis is clearly entitled to very serious consideration, yet it has rarely been considered seriously outside the works of the authors themselves It is easy to find reasons for this, but difficult to find excuses We hope the pamphlet will make it unnecessary to look for them in the future

Very pertinent also are Prof Moulton's remarks concerning the significance of formulæ A mathematical statement undeniably carries with it an air of authenticity which does not usually accompany general descriptions, although the latter may involve greater imaginative insight and approach more nearly to the actual happenings of Nature In the attempt to reconstruct cosmic history, the inquirer may be actuated by either of two motives he may believe that something actually occurred in pre human times, and seek to discover what it was, or he may be concerned to weld together observed phenomena into a consistent logical scheme, and introduce the past as a useful parameter without necessarily assigning to it the dignity (or indignity) of actuality Usually, perhaps always, the two motives are mixed, but on the whole the former predominates in the descriptive, non mathematical theorist, and the latter in the mathematical physicist So long as our knowledge is partial, at least, the two motives will urge the inquirer along diverging paths We are glad that Prof Moulton has had the courage to insist that one is not inevitably more valid than the other

Having made so clear a distinction, however, Prof Moulton most surprisingly fails to preserve it, and as a result we have his vigorous criticism of Jeans and Jeffreys which his own general principles, if properly applied, would discredit The starting-point and sole sanction of the attack is the assump-

tion that the 'tidal theory' of these writers is merely a vain attempt to formularise the planetesimal hypothesis and consequently is separated by a profound gap from hypotheses of the Laplace type It is difficult to understand how such an assumption could be made, for there could scarcely be a more typical example of the Laplacian type of hypothesis than the tidal theory It has, in common with the planetesimal hypothesis, the assumption of a passing star as the origin of the whole process, but the sub sequent development is so profoundly different in the two lines of thought that the bodies which give the name to the hypothesis of Chamberlin and Moulton do not exist in that of Jeans and Jeffreys

Extracts from prefaces will perhaps make this clear Jeans writes "The present essay is primarily an attempt to follow up a line of research initiated by Laplace and Maclaurin, and extended in various directions by Roche, Lord Kelvin, Jacobi, Poincaré, and Sir G Darwin" Prof Moulton's examples of the Laplacian type of hypothesis are the works of Laplace, Helmholtz, Sir G Darwin, and Lord Kelvin Jeans continues When a firm theoretical framework had been constructed, it seemed permissible and proper to try to fit the facts of observational astronomy into their places" Chamberlin, on the other hand, was led to theoretical discussion by a desire to explain geological facts "We may make the vestiges of the genetic events serve as our guide All the peculiarities of the planetary system should serve as system pointers to the true interpretation"

Again, Jeffreys writes "Quantitative comparison of theory with fact has always been the main object of the book" Clearly it is the 'formula' type of theory that is attempted here

Prof Moulton's attack on Jeffreys's 'tactics' is regrettable and, it appears to us, without justification It is unfortunate that Jeffreys does not give a specific date to Chamberlin and Moulton's work, but the character of his discussion of it is not fairly indicated in the pamphlet After very favourable mention in Chap ii it is discussed in an appendix of seven pages beginning "The Planetesimal Hypothesis was historically the parent of the Tidal Theory It was invented by T C Chamberlin and F R Moulton in the early years of the present century, and detailed accounts of it may be found in" (three sources) Since Prof Chamberlin gives 19 references to original papers on the hypothesis, excluding its exposition in books, Jeffreys's date is perhaps as specific a one as could conveniently be given, and should certainly mislead no one in the matter of priority The historical importance of the hypothesis is again emphasised at the end of the appendix

We are convinced that Prof Moulton's charge of national jealousy is unfounded, and the foregoing quotations appear to us to be strong evidence on this point It will nevertheless be appropriate to examine the matter more generally An analysis of the personal references in the indexes of the books here considered reveals the following percentage figures

	References to		
	English Writers	American Writers	Others.
Chamberlin	13 1	65 6	21 3
Jeans	22 8	37 9	39 3
Jeffreys	58 6	16 8	24 6

Prof Chamberlin s book has been included not in order to criticise his neglect of non American work, but to show the inevitability of an apparently undue emphasis on the work of one s own country men in any original investigation We do not complain of Prof Chamberlin s tactics we go to his book for an account of the planetesimal hypothesis which was indisputably made in America But we do think that Sir James Jeans and Dr Jeffreys are entitled to a similar consideration Their theories are as original as Prof Chamberlin's, and we hope that Prof Moulton's just objection to a general neglect of Prof Chamberlin's work will no longer be weakened by an unjust attack on the work of others

The Study of Corals

Catalogue of the Madreporarian Corals in the British Museum (Natural History) Vol 7 *A Monograph of the recent Meandroid Astræidæ* By Prof George Matthai Pp v + 288 + 72 plates (London British Museum (Natural History), 1928) n p

THE existing corals are the most unsatisfactory group of the animal kingdom from a systematic point of view They are accursed in that they have supposed ancestors and relations so far back as the early Cambrian, the play of stratigraphers, who care not for life Their most prominent feature is an exo skeleton of carbonate of lime, which is neither for protection nor for muscular attachments, both of which are reflected in those of vertebrates and arthropods There are radiating plates (septa) from centres, over which lie the mouths (stomodœa) of the anemones (polyps) that are seated upon them Other structures are central columns (columella) and surrounding walls, all free edges toothed perhaps, and the skeleton (corallum) goes on perpetually thickening so long as the

anemones live There is immense variation in the size and height of septal teeth, and the septa vary in length, height, and thickness, as do all other structures, in correlation with rapidity of growth, with incidence of light, with water movements, and so on Systematy becomes worse in 'colonial or many mouthed or polyped forms, for these show in addition, more clearly correlated with environment, variation in the position and rate of production of new polyps such as to give wide differences in the coralla All modern reef builders have algæ living and reproducing within their polyps, and these we judge to be the most important factor in their nutrition They, like the chlorophyll in the tree, may produce vast modifications in the growth form of their host

Yet modern corals must be classified for the sake of the palæontologists who have to make their deductions as to the fossil species from the analogous living forms, if for no other people About half a century ago their skeletons were all we really knew They were supposed to be internal before von Koch found them to be formations or precipitations outside the animals Then the anatomy of the polyps was partially cleared up by von Koch and by von Heider Fowler, Bourne and Duerden amongst others, while Wayland Vaughan, by his studies on both living and fossil corals, greatly enriched our knowledge The barrenness and inadequacy of any systematic study based on corallum alone was made clear Yet, to bring conviction, the attempt had to be made to bring order out of confusion on the old lines, and the Natural History Museum issued six catalogues dealing with eight genera Brooks and Bernard made confusion worse confounded The latter never examined scientifically even a single coral polyp, and yet stated that their skeletons 'follow the growth of the polyps closely ' He was unable to determine his species and adopted a geographical arrangement, for example, enumerating twenty four forms, which he termed Porites Fiji Island, 1–24 ", growth forms are correlated with localities rather than with environments These catalogues were misfortunes, sheer waste of money, which could have been avoided if any member of the Museum staff had been sent to any coral reef for six months' study of the living forms

It was at this stage that Prof Matthai commenced his researches eighteen years ago He made a profound study of polyps and coralla together, specialising on the massive, many polyped Astræidæ, some of which have separate seats for each polyp, separate corallites, while others have meandering valleys with many stomodœa Of the former he had more than eight hundred specimens in the collections at Cambridge, and he examined the polyps of seventy five of these by sections He also worked over the collections of Glasgow and of most of the European capitals, in which he found 590 colonies His results (*Trans Linn Soc*, **17**, 1914) reduced the described species by three-quarters, and he showed that, once the polyp form of a species was determined, the species could be recognised by coralla alone Hermaphroditism was seen to be a common phenomenon, and fission of the polyps by division through their stomodœa was proved not to exist, thus upsetting a main character in all former classification

Prof Matthai then extended his researches to the reefs of the West Indies and, *en route*, examined many of the Dana and other types in the United States His Colony Formation in Astræid Corals ' (*Phil Trans R.S*, 1926) sets out two modes of polyp budding, inside and outside their tentacular rings The extratentacular budding corals have only a single stomodœum within each circle of tentacles, whereas the intratentacular are di , tri , or poly stomodœal, the stomodœa joined to each other by either one or two couples of mesenteries The foundation of the long meandering valleys of the brain corals was made clear *Hydnophora* is the extreme case its monticules are isolated bits of corallite walls, while the polyp surface between has vast numbers of stomodœa, the 'colony' being really a single poly stomodœal anemone, seated on a coral base of complicated plates and walls

The systematic examination of the vallied Astræidæ was the test required for these results The Cambridge collections, both of these and of the genera previously examined by Matthai, were given to the Natural History Museum, together with all sections, etc , for permanent reference The Museum at once offered to print a catalogue, and this has now appeared, with such a wealth of illustration that, be the system correct or not, we have a mass of information from which any subsequent researcher may conveniently start Matthai's services were given under considerable personal sacrifice, but he should be satisfied with the results, which reflect the highest possible credit on himself and on the Indian Educational Service to which he belongs This is a strong statement, but I confess that I was sceptical as to the application of his theoretical paper to systematy As a result, I have been testing his methods and conclusions as to the species of his corals off and on, since I first learnt them, more than a year ago I

find they work with comparative ease, and I have no advantage over any other systematist save a very limited acquaintance with corals as living organisms

The secret expounded by Matthai is first to study the polyps, none of which have directive mesenteries, to determine how they form fresh mouths, and this gives the clue to valley formation, etc He finds the same methods in quite diverse colonies, these form a genus to be further divided into species on other anatomical characters The mesenteries joining stomodœa, the varied forms of nematocysts, and the number of principal mesenteries are some of the accessory characters of his polyp key Those chosen for the skeleton key are septal margins toothed or not septa thick or thin columella present or absent, and lamellar, dense or trabecular, etc these unfortunately, bear a minimal relationship to the growth methods of the polyps, with which the mesenteries of the first key are concerned Each key will help the systematist to name, but the corallum key gives no clue to the phylogeny of the group, as to which the author rightly speculates The interesting fact appears that of the 28 genera described, 16 are confined to the Indo Pacific and 12 to the Atlantic their centres respectively in the East and West Indies Ten of the genera are monotypic, while 10 others have 2 species each Of the more abundant brain corals the Indo Pacific *Cœloria* has 4 species (2 new) in place of 16, and the Atlantic *Mœandrina* 3 in place of 28 *Mussa* of the West Indies—it is a pity that Matthai could not obtain polyps—is stated to be monotypic, whereas its supposed Indo-Pacific forms are placed in three species of *Lobophyllia*, which would be easier to follow were their numerous figures less scattered in the plates

In conclusion, we congratulate the Directors and the Keepers of the Natural History Museum that have been concerned on their bravery and scientific acumen in recommending the publication of this catalogue, after six previous quite disastrous volumes The refiguring by photographic methods of a large number of 'type specimens' in many museums is of immense value, and only made possible by the recognition that science is international This shows a healthy spirit in zoological science, as does the co operation of directors and collectors with a real worker On the whole, I am disposed to consider that the method here sketched is almost the last word so far as the anatomy of 'wild' species is concerned, and for the next advance I look to experiment and to a study of the whole physiology of coral polyps, particularly to that of corallum formation That many species are adapted to wide changes in salinity, in temperature, in currents, in mud content of the water, in light, in phosphate content (especially in connexion with the commensal algæ), etc, is certain All these are felt by the living polyps and are reflected in the growth of large colonies We must know here more about our living beasts before we study further their systematy

J Stanley Gardiner

The Origins of European Culture

The Most Ancient East the Oriental Prelude to European Prehistory By Prof V Gordon Childe Pp xiv + 258 + 24 plates (London Kegan Paul and Co, Ltd, 1928) 15s net

A NEW book by Prof V Gordon Childe is always welcomed by students and the volume under notice has special value as it carries the history of European cultures as described in his Dawn of European Civilization" (1925) to their origins in the ancient East for the whole chronology of prehistoric Europe ultimately rests on synchronisms with the historical cultures of Babylonia and Egypt The book begins with a reconstruction of the culture of the then thickly populated pleasant grass lands of northern Africa and southern Asia of late palæolithic times Firm ground is reached in the description of the culture recently found at Badaria, south of the Fayum Culturally, the immigrant Badarians were a whole stage removed from the savagery of the Capsian hunters, they had mastered all the arts that are usually termed neolithic, and in addition they were acquainted with copper The Badarians may have been autochthonous in the Nile valley or somewhat farther east, the modern Hadendoa appear to have relations with this ancient stock They were the founders of Egyptian agriculture Later, the first pre dynastic culture arose in Upper Egypt from this basis and an infiltration of Getulian elements from the west

The First Dynasty of Babylon can be fixed at 2196 B C, but long before this there are written records of kings of various cities that date back to an event termed the Flood, and even earlier The First Dynasty of Ur dates from before 3000 B C, and belonging to a period some 500 years earlier are the royal tombs excavated by Mr C L Woolley Those who have seen his exhibitions in the British Museum will recognise that this very rich and mature civilisation must have had a long history behind it Gordon Childe discusses the character and affinities of the first and second prediluvial

cultures, the former is mainly revealed from excavations at Susa (S I) and at al'Ubaid, the latter is that of Susa II and of other sites

As we have the first account in book form of the Badarian culture, so also we have that of the Indus civilisation We find thanks to work of Sir John Marshall on the now impoverished banks of the Indus a brilliant civilisation in touch at once with the prediluvial villages of the Iranian plateau and the nascent city states of Babylonia, and the Arabian Sea was ploughed by dhows freighted with the stuffs of Sindh consigned to Babylonian river towns Thus the civilisation of Sindh was ahead of that of Sumer About 3000 B C a catastrophe over took the cities of the Indus basin Gordon Childe thinks it is a legitimate deduction that the rôle of the maritime peoples of Arabia was to act as intermediaries between Egypt Mesopotamia and India

This book should be of definite interest to the non specialist reader as it is pleasantly written copiously illustrated and will enable him to place in their historical setting the discoveries that are continually being noticed in the daily Press

Our Bookshelf

Morpheus or the Future of Sleep By Prof D F Fraser Harris (To day and To morrow Series) Pp 94 (London Kegan Paul and Co, Ltd New York E P Dutton and Co, 1928) 2*s* 6*d* net

A NUMBER of eminent men of science have contri buted to the admirable series to which this little book belongs, and success has attended their efforts varying with their ability to cast aside professional restraints and speak their adventurous and un guarded minds If the unsophisticated reader is willing to add Dr Fraser Harris's name to the list, it will be for reasons which are unfortunately con cealed from the specialist No subject could offer a greater opportunity for daring and ingenious speculation founded in scientific fact but Dr Fraser Harris prefers to follow (rather lamely) the story of the journals On p 11 expectation is aroused by the statement that comparatively few people could tell us exactly what it is that makes us sleepy and finally permits us to go to sleep' Gall, Mosso, Pupin, Claparède, Ramon y Cajal, Duval, Howell, Coriat, and Pavlov did not claim to do more than suggest tentatively, and while the author gives some account of their work, it is for the most part shorn of those honest doubts and reservations which somehow constitute a real contribution to the subject Finally, he takes refuge in that disastrous propensity of physiologists confronted with conflicting streams of evidence, the 'omnibus' theory Thus we have the absurdity 'types' of sleep (p 26) Par ticularly it is confusing to see Pavlov taken into the omnibus First among physiologists he seems to have broken with the earlier inactivity theories completely There is still the problem of sleep

Some serious errors are made The granules of Nissl are scarcely 'rod like' and they certainly are not to be found in the nuclei of nerve cells in any circumstances, as Dr Fraser Harris implies (p 25) The dream does not appear to have a very respectable biological ancestry if all we can say is that we are entitled to assume that certain animals for instance the dog, can dream" For many animals the dream is a most important pro tective mechanism The speech centres in the frontal lobes does some injustice to several workers and it is to be doubted whether insistence upon the hallucinatory character of dream images is to be commended even in a popular work Several passages suggest that Dr Fraser Harris has not observed the manias associated with low blood pressure Whether there seems no reason to doubt that information is conveyed telepathic ally or directly to the brain without having been communicated through any of the sleeper's organs of sense (p 77) is a matter of opinion as is also the statement that some dreams are the expres sion of ancestral memories is an attractive theory' (p 78)

The future of sleep is discussed in sixteen pages Evidently its security will depend largely upon social and political agitation for the suppression of its prolific modern enemies

Elements of Alternating Currents and Alternating Current Apparatus By Prof J L Beaver Second edition Pp xiii + 393 (New York, London and Toronto Longmans Green and Co, Ltd 1928) 18*s* net

THIS book is written mainly for the benefit of those commencing the study of alternating currents The numerical examples are numerous and a very fair attempt has been made to explain away the difficulties which every one experiences in studying the subject For those who have not the benefit of a teacher numerous references are given to papers and other text books where fuller explana tions will be found Some of these papers, as for example the *Bulletins* of the General Electric Company of America cannot easily be obtained on the eastern side of the Atlantic The nomen clature used is mainly that standardised in America Capacity is called capacitance and a condenser is sometimes called a 'capacitor' Possibly this is to prevent confusion with a steam condenser, which is quite a different device It has long been thought desirable by electricians to standardise the termination 'or' to designate a piece of apparatus But the difficulties in the way seem insuperable Arrestor, startor, and divertor are coming into use, but exciter, damper, and feeder still have the 'er' termination

Naturally, in an elementary book it is difficult, if not impossible, to state the theorems rigorously and to give their limitations We think, however, that a word of warning might have been added on

p 166 to the formula given for eddy current losses On p 44 it is misleading to state that the 'convex surface' of a conductor carries the high-frequency current In a concentric main with high-frequency currents the current nearly all flows near the concave surface of the outer conductor, the current near its convex surface being almost negligible On p 107 the method of representing a vector by a complex number is attributed to Dr Kennelly Mathematicians usually attribute it to J R Argand (1806), but it seems to have been previously used by Gauss and Wessel (1797)

L'Industria chimico metallurgica del solfato di rame e le miscele cupriche funghicide ed anticrittogamiche Per E Crivelli Pp viii + 321 (Milano Ulrico Hoepli, 1928) 35 lire

This is an interesting book, which can be heartily recommended to makers or users of copper sulphate, to all chemists, and, as regards some sections of it, to the general reader

Part 1 deals with the development of the blue vitriol industry and with its marketing, methods of analysis and properties, and contains also a detailed description of its manufacture, including treatment of by products In Part 2, the metallurgy of copper, in so far as it concerns the manufacture of the sulphate, is considered, and in Part 3, such subjects as its physiological effects, its mode of action in lime–copper sulphate pastes, its uses as an anticryptogam, and various minor applications, are discussed

The book has been carefully written and, although the information given must be almost exhaustive, is far from being a mere compilation, the material being dealt with in a logical and readable manner To the majority of readers, probably the most interesting portions of the book are those of Part 3, in which the available experimental data concerning the effects of copper salts on animals and plants are subjected to critical examination

No index is provided, but this lack is largely compensated for by the table of contents A few minor misprints occur, and the first logarithm given on page 52 for $CuSO_4$ is actually that of the pentahydrated salt The printing is of the usual high Hoepli standard

An Atlas of Economic Geography (Text and Maps) By John Bartholomew and Prof L W Lyde Third edition, revised and enlarged in co operation with M R Shackleton Pp xciii + 74 (London Oxford University Press, 1928) 8*s* 6*d* net

This is more than an atlas of economic geography, for the text runs to nearly a hundred pages, and besides explaining the maps, adds a great deal of useful geographical matter It is full of ideas, and points out many striking geographical correlations Prof Lyde is responsible for the whole of the text The number of coloured maps is slightly reduced from the original edition, but two dozen black and white distributional maps have been added In these, as in the coloured maps, the technique is excellent and the standard of accuracy is high Minor changes might be made in the map of religions and of commercial development, and it is to be hoped that in the next edition the colour division of the races of man may be abandoned Another improvement in a most useful work would be the re introduction of the maps of seasonal distribution of rainfall and of languages of commerce

Stage A Geometry By R W M Gibbs (Black's Mathematical Series) Pp viii + 109 (London A and C Black, Ltd, 1927) 2*s*

All teachers will recognise the importance of the Mathematical Association's Report on "The Teaching of Geometry in Schools," and the value of Mr Gibbs's work lies in his successful attempt to provide a suitable text book to cover Stage A as recommended in the Report The arrangement of subject matter and the selection of examples show that the author is used to the practical difficulties of approaching the subject of geometry for the first time

Emphasis is naturally laid on the experimental aspect, and field work, and what is sometimes known as 'boy scout geometry,' are well treated In addition to general ideas on mensuration, including Pythagoras's theorem, the book concludes with introductions to symmetry, loci, and similar figures This volume should form an excellent stepping stone to the other stages, deductive and systematising, mentioned in the Report

H D A

Volumetric Glassware By Verney Stott (Books on Glass and Glass Technology) Pp 232 (London H F and G Witherby, 1928) 20*s* net

This work comes as a wholesome corrective to those trustful chemists and physicists who are tempted to accept their volumetric instruments even with a modicum of faith The author emphasises the importance of quality and accuracy in volumetric glassware, and his book is intended for manufacturers and users of such apparatus Various common types, including measuring flasks, graduated cylinders, pipettes and burettes, are treated in detail, and a description is given of the processes of marking and graduating Other essential subjects, such as units of volume, calibration tables, and the effect of apparatus errors on results, are also adequately treated The book, which contains numerous illustrations and tables, can be recommended to all who are concerned with volumetric analysis and similar work

School Researches in Heat By C W Knight Pupil's Book Pp ii + 96 1*s* 3*d* Teacher's Handbook Pp 80 1*s* 6*d* net (London George Philip and Son, Ltd, Liverpool Philip, Son and Nephew, Ltd, n.d)

Little books which follow the author's method of teaching heat to an elementary standard by means of questions and answers They are good in their way, though somehow the spontaneity which the method demands seems dulled by the formality of print

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Nervous Impulse in *Mimosa pudica*

Is the conduction of the excitatory impulse in the plant essentially similar to that of the nervous impulse in the animal? This problem is of great theoretical interest. In his "Nervous Mechanism of Plants" (1926), Bose states that the intercommunication and interaction between more or less distant organs in the plant are brought about, as in the animal, "in two different ways—by translocation of matter and by transmission of motion. The first is effected by the *slow* movement of fluid carrying chemical substances in solution, such as occurs in the circulation of sap; the second by the *rapid* propagation of protoplasmic excitation such as the nervous impulse in the animal." In his presidential address at the Indian Science Congress, Lahore (1927), Bose makes his position perfectly clear by the statement that in physiological investigations the inquirer is primarily concerned *with the function of the organ and not with its outward form*. In support of this he adduces the case of insectivorous plants (*Drosera*, *Dionæa*, and *Nepenthes*) which are universally acknowledged to possess digestive organs, in spite of the fact that the organs are very different in appearance from those of the more complex animal. The employment of the same term for these plant and animal reactions is justified by the fact that the function of digestion is performed by similar processes in both: the solution of organic food material by a glandular secretion, and the subsequent absorption of the dissolved product.

The plant-world offers a unique opportunity for the study of the gradual evolution of a simple and primitive organ into one of greater complexity. In regard to the nervous function, it is to be remembered that the conducting tissue in the animal kingdom itself exhibits wide variation from the simpler type as in the Medusæ to the more complex in the higher animals. The conducting tissue of the plant would naturally be expected to be much simpler in structure, and as a matter of fact it is very different in appearance from the nerve of the higher animals. The question to be decided is whether or not the process of conduction of excitation is similar in the two cases (being usually detectable by the contractile movement of the terminal motor organ).

There are several physiological tests of a crucial character by which the nature of the transmission of the impulse in *Mimosa* can be ascertained, whether it is dependent upon a movement of sap, or is a conduction of protoplasmic excitation. Sir J. C. Bose has been kind enough to offer me every facility for working in his Research Institute at Calcutta, and an account of the following experiments on transmission of excitation in *Mimosa* will doubtless be of interest to readers of NATURE. It may be stated that the series of experiments which I repeated were accomplished without a single failure. Limitation of space allows me to describe only one typical example of each series.

The experiments were carried out in winter (January 1929). Though the physiological condition of *Mimosa* was not so favourable as in summer, yet I encountered no difficulty in obtaining the following results in a green house (temp. 30° C.) in which the sunlight was uniformly diffused by glass thinly coated with white paint.

EXPERIMENTAL SERIES 1. *Discriminative Polar Action of Electric Current in Excitation.*—In an animal nerve, a feeble electric current initiates excitation at the cathodic point at 'make' (there being no excitation at the anode); the transmitted excitation is detected by the twitch of the terminal muscle.

In the parallel experiment with *Mimosa*, I made suitable electric connexions with two opposite petioles at a distance of 20 mm. from the motile pulvinus. When the point on the right petiole was made the cathode, an excitatory impulse was generated which, travelling against the direction of the normal transpiration current reached the pulvinus and caused the fall of the leaf after an interval of 1.5 sec. Making allowance for the latent period of the pulvinus, the velocity of transmission of excitation in this winter specimen was found to be 14.3 mm. per second. Reversal of the direction of the current by a Pohl commutator caused cathodic stimulation of the left petiole, resulting in the fall of that leaf.

Similar results were obtained with the secondary petiole of a leaf, in which the propagation of the excitatory impulse is exhibited by the upward closure of the sensitive leaflets (Fig. 1). Bose found that the

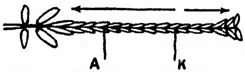

FIG. 1.—Effect of feeble current. *K*, cathode; excitation transmitted across feeble anode *A*. Arrows indicate directions of propagation of impulse which ultimately causes closure of all leaflets to right and left.

velocity of transmission in *thin* petioles is very much higher, being 100-350 mm. per second. My results fully confirm this.

It will be noted (1) that the impulse was transmitted in the complete absence of any hydromechanical disturbance; (2) that excitation was originated and conducted without any wound which might have induced the secretion of some hypothetical stimulant which could be translocated by the movement of sap; (3) that the direction of transmission of impulse was inwards, against the direction of the normal transpiration current; (4) that the speed of transmission was incomparably higher than that of the slow movement of sap; and (5) that the characteristic polar action of the current which initiates nervous impulse in the animal also caused an excitatory impulse in the plant.

EXPERIMENTAL SERIES 2. *Arrest of Conduction by Anodic Block.*—With feeble current, the impulse in the animal nerve is transmitted across the anode; but with a stronger current, the depression of conductivity at or near the anode is so great that the impulse is arrested by an anodic block.

In *Mimosa*, parallel effects can easily be demonstrated in the secondary petiole, conduction taking place in both directions as in the nerve. On starting a feeble current (1.4 microamperes), the cathodic excitation at *K* was transmitted (Fig. 1) to the right and to the left (across the feeble anode). The experiment was repeated with a stronger current (3.5 microamperes), the impulse initiated at the cathode *K'* was now transmitted to the extreme right end of the secondary petiole, whilst the impulse to the left was

completely arrested at A' by the depression of conductivity caused by the stronger anode (Fig 2)

EXPERIMENTAL SERIES 3. *The Reflex Arc*—The phenomenon of the reflex arc is well known in the animal, where the afferent or ingoing impulse due to peripheral stimulation is reflected at a centre and is transmitted along a new path as an efferent or out going impulse

It is very surprising that exactly parallel effects are observable in *Mimosa* Peripheral stimulation of the

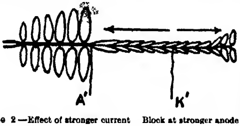

FIG 2—Effect of stronger current Block at stronger anode *A*

secondary petiole (1) at *S*, by tetanising electric shock of moderate intensity (Fig 3), gives rise to an ingoing or afferent impulse, which reaches the pulvinus and causes the fall of the leaf After a short while, the existence of an efferent or outgoing impulse is detected by the serial fall, from base towards apex, of the leaflets on the secondary petiole (2) There is a marked difference between the velocities of the ingoing afferent and of the outgoing efferent impulses Bose found it to be about seven times greater In the experiments which I carried out I found it to be six to eight times quicker

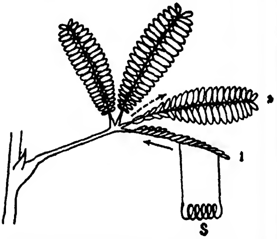

FIG 3—The reflex arc Peripheral stimulation of secondary petiole 1 at *S* causes afferent impulse (continuous arrow) which after reflection at pulvinus gives rise to efferent impulse (dotted arrow) in secondary petiole 2

As all the characteristic effects of the transmitted impulse in *Mimosa* are in every way similar to those of the nervous impulse in the animal, the most natural inference is that the process of transmission is of the same nature in both Physiologists will therefore be inclined to agree with Bose's conclusion, that if the impulse be called 'nervous' in the animal, there is equal reason for applying the same term in the case of the plant

Growth-gradients and the Development of Animal Form

D'ARCY THOMPSON in his "Growth and Form," Chapter xi, deals lucidly with the properties of logarithmic spirals, and the reasons for their frequent occurrence in organisms He points out that for them to arise, (1) parts of the growing edge must be growing at different rates, the growth rates of any two points on the edge preserving a constant ratio of growth rates for so long as a regular logarithmic spiral is produced, (2) the growth rate must fall off more or less steadily from one end of the growing surface to the other, (3) the products of growth must be laid on as so much dead matter, or at least matter incapable of further growth. In his own words (p 500) the logarithmic spiral form of an organic structure can be explained "if we presuppose that the increments of growth take place at a constant angle to the growing surface, but more rapidly at the 'outer edge' than at [the 'inner edge'], and that this difference of velocity maintains a constant ratio Let us also assume that the whole structure is rigid, the new accretions solidifying as soon as they are laid on"

It is, I think, worth pointing out that this and the type of growth which Champy (C Champy, "Sexualité et Hormones," Doin, Paris, 1924) and I (J S Huxley, *Biol Zentralblatt*, Bd 47, p 151, 1927) have called heterogonic (in which the size relations of organs x and y can be represented by the equation $y = bx^k$) are both special cases of the same phenomenon namely, of constant differential growth ratios in different regions of the organism The sole difference is that in logarithmic spiral growth the increments produced take no further part in growth, but are locked up as so much rigid structure, while in heterogonic growth the increments are added to the mass of living tissue capable of continued growth The difference is similar to that between two sets of sums of money growing at different rates of simple interest and at different rates of compound interest respectively

There is a further interesting similarity between the two types of differential growth In logarithmic spiral growth, the growth rates fall off more or less evenly from one margin of the growing surface to the other I have succeeded in showing (*l c* and unpublished work) that in markedly heterogonic organs such as crustacean chelæ (*Uca*, *Maia*, *Homarus*, *Eupagurus*, various prawns, etc) the most rapid growth rate is that of the penultimate joint, the growth rates of the other joints falling off regularly as the body is approached Similar facts appear to be true for the limbs of ungulates, according to my friend Mr J C Hammond, and the abdomen of female spider crabs (M E Shaw, *Brit J Exp Biol*, 6, 145, 1928) When, on the other hand, growth is isogonic, all the parts (joints of female chela, *Uca*, *Maia*, joints of male abdomen, *Inachus*) grow at the same rate

As I previously pointed out, and as has been stressed by Pearsall (W H Pearsall, "Growth Studies" 6. "On the Relative Sizes of Growing Plant Organs," *Ann Botany*, vol 41, No 163, pp 549 556, 1927) in his analysis of similar heterogonic relations between the parts of plants, heterogony is really the simplest type of differential growth, occurring, namely, when the ratio of two growth rates remains constant over long periods It is interesting to find that one of the other most generally distributed modes of growth, that in the form of a logarithmic spiral, is deducible from the same principle. Various shells depart slightly from the strict logarithmic spiral, and various disharmonically growing organs depart slightly from the accurate heterogonic formula. But this does not obscure the basic nature of the differential growth-ratio

It would further seem to be a general principle that when two regions of markedly different growth rate exist in an organ or region, there is a graded change of growth rate in the intermediate space The bio chemical basis of such graded differences in growth rate should be interesting to investigate

Difference between the Absorption and the Raman Spectrum

Several investigators have recently stated that in many cases Raman lines are found which do not correspond with infra red absorption frequencies (Carelli, Pringsheim, and Rosen, *Zs f Phys*, 51, p 511, 1928 Czerny, *ibid*, 53, p 317, 1929 McLennan and McLeod, Nature, 123, p 160, 1929 Ellis, *ibid*, p 205 Rasetti, *ibid*, 205 R W Wood, *ibid*, p 279, and others) Several authors state this as contrary to the theoretical expectations The purpose of this note is to direct attention to the fact that the above mentioned phenomena, far from being a contradiction to the theory, really furnish a very good proof for the validity of the Kramers' theory of dispersion, which includes the theory of the Raman effect

If we consider two levels A_1 and A_2 we have absorption if the transition coefficient a_{12} is different from zero But this coefficient does not enter at all into the expression which determines, according to Kramers and Heisenberg, the intensity of the Raman line From the fact that this coefficient is zero, one cannot therefore conclude that the corresponding Raman line must be absent and vice versa The intensity of the Raman lines is determined by the transition coefficients to levels B_1, B_2, B_3, etc, which can combine with both A_1 and A_2 The Raman fre quency can therefore always be regarded as the difference between the frequencies of two lines, one of which must be an absorption line, and this in agree ment with the results of Rasetti and especially with those of McLennan and McLeod A very good ex ample is also furnished by the beautiful results of Wood in hydrochloric acid Wood finds that the so called missing line occurs with great intensity in the modified radiation, whereas the real lines of the ab sorption band are faint and doubtful

This is exactly what we must expect For let us consider a hydrochloric acid molecule in a definite rotational state j, and confine ourselves to the different vibrational and rotational states of the normal molecule Then there is, on account of the selection rule for j, not a single state which can combine at the same time with the j and the $j \pm 1$ rotational state, or differently expressed, an absorption line of the HCl band cannot be written as the difference of two other lines and therefore ought not to occur in the Raman spectrum On the other hand, every transition in which the rotational quantum number j does not change or varies two units (the *vibrational* quantum number varies from zero to one for all lines under consideration) can be written in more than one way as a difference of two line frequencies We must, therefore, expect these frequencies in the Raman spectrum rather than the frequencies of the absorption band The transitions in which j does not change give the 'missing line' and are forbidden as absorption lines Raman lines corresponding to transitions $j \longrightarrow j \pm 2$ must be expected very much weaker, as they are distinct lines for different values of j with twice the distance of the absorption lines, whereas all the $j \longrightarrow j$ transitions correspond to lines which coincide on the place of the zero line and give rise, therefore, to one intensive line This seems to be in agreement with Wood's observations Rotational transitions $j \longrightarrow j + 2$ of the expected type seem to have been observed by McLennan and McLeod in H_2 If also the ultra-violet absorption bands, of which nothing is known, are taken into account, these considerations have to be modi fied a little But from the general structure of the molecular terms it can be deduced that, for diatomic molecules at least, an absorption line never can be expected as a Raman line Apparent exceptions to this rule find their explanation in an unresolved fine structure

With the same considerations one sees that scattering in sodium vapour ought to give a shift corresponding with the forbidden line $1s - 2s$ rather than with the absorption line $1s - 2p$

Since the above was written, I have seen the letter by Langer in Nature of Mar 9, p 345, in which he makes essentially the same observation But as he treats only a rather complex example and proceeds according to somewhat different lines of reasoning, the present note is perhaps not superfluous It ought to be mentioned also that Schrödinger's theory of dispersion in its original form is, contrary to Langer's statement, not in agreement with the facts, whereas the present form of quantum mechanics (Dirac) leads exactly to Kramers and Heisenberg's results

Breeding Habits of the Greenland Whale

Very little is known about the breeding habits of the Greenland whale In the Greenland Sea, according to the log books of Scoresby Sen, females with calves with them were seldom seen except in spring, west of Spitsbergen, north of latitude 78° or 79°, and in the end of July off the Greenland coast Young whales, with whalebone 2 3 feet long—the smallest which are seen by themselves—were also seldom seen except in a high latitude west of Spitsbergen in spring Where they go to in the summer months is not hard to understand as my father says, "the old females with the younger whales of both sexes bury them selves in the polar ice, north of latitude 80°, after (or before) the end of June, where no ship can follow them, retreating in the autumn southwards as the ice makes in the north" (Scottish Fishery Board, Seventh Annual Report, part 3, p 366)

A female with a calf with it became a rare sight in the Greenland Sea, in twelve voyages (1791–1798, 1801, 1817, 1820, and 1822) Scoresby Sen saw one only on sixteen dates, namely, west of Spitsbergen, and north of 78° or 79° in April once, in May eleven times, and in June once, and off Greenland twice, both times at the end of July, in latitude 70°, in the forty four voyages he was master (1849–1891 and 1893) my father only saw about a dozen (*l c*, p 365), and in his last twenty voyages only one (in the end of July in latitude 73° off the Greenland Coast), and in the log books of twenty nine other voyages made in the period 1872–1908 not a single instance is recorded

There are few facts to go on, but it seems safe to infer from what the Scoresbys and from what Eschricht and Reinhardt say, that at least some of the young are produced in the spring Even less is known about where they produce, at one time they entered the inlets of western Spitsbergen in the summer months, and Sir Sidney Harmer (*Proc Linn Soc*, May 1928, p 89) connects their visits with the function of

parturition and looks on the unmolested use of the Spitsbergen bays as of importance to them, this, however, seems unlikely for the following reasons

1 In the spring, when some, possibly all the whales of the species, as Scoresby suggests, produce their young, the sheltered parts of the west Spitsbergen inlets are usually still covered with the ice that forms in the winter months

2 In Davis Strait, according to Eschricht and Reinhardt, the corresponding visits of the species to the inlets of west Greenland synchronised with the proximity of the pack ice to the coast and were not connected with parturition

3 In the Greenland Sea and in the waters west of Spitsbergen (the 'Greenland' of the old whalers), contrary to what Sir Sidney Harmer states (*l c*, p 59), the fishery continued productive for long after the whales ceased to enter the inlets and bays, in the ten seasons (1679–1688) (thirty or forty years after) the 'Greenland' fleet of the Dutch, numbering about 190 ships, alone captured 10,019 whales (Scoresby, vol 2, p 156), and so late as 1814 in the same waters 76 English and Scotch 'Greenland' ships alone captured 1413 in a single season (*ibidem*, p 121)

Sir Sidney Harmer seems to imply that the females with calves with them not only entered the Spitsbergen bays, but also were destroyed in these situations in large numbers by the early whalers, this, again, seems unlikely, for in the seventeenth century the whalers do not appear to have arrived at Spitsbergen until the end of May, and after the time at which the females with calves with them usually disappear amongst the impenetrable polar ice, a separation of the sexes seems to take place in the summer months, and it seems more likely that the whales that entered the Spitsbergen bays and were killed by the early whalers (if they all belonged to this species) belonged mostly to the male sex ROBERT W GRAY

Exmouth

Nuclear Levels and Artificial Disintegration

THE existence of quasi discrete levels in the atomic nucleus has been suggested by Dr Condon and myself in a paper in the *Physical Review*, in which the nuclear theory first outlined in NATURE, Sept 22, 1928 (vol 122, p 439), is pursued These quasi discrete levels are narrow ranges of energy for which the amplitude of the ψ functions inside the nucleus is large compared with the amplitude outside In a very interesting letter in NATURE of Nov 24, 1928, G Gamow, who in other respects had arrived quite independently at the same basic ideas with regard to the nucleus (*Z f Phys*, **51**, 204), gave a résumé of various applications, including that of artificial disintegration, a detailed account of which has since appeared (*Z f Phys*, **52**, 510) Considering the intensities of the transmitted and reflected waves, he inquires how the probability of penetration into the nucleus will fall off with decreasing velocity of the incident α particle, treating the nucleus as a simple potential barrier, he naturally finds that the probability shows a steady decrease

The object of the present note is to direct attention to the possibility of resonance phenomena if we take into account the solutions of the Schrodinger equation which for certain ranges of energy give ψ functions the amplitude of which inside the nucleus is large compared with that outside For this seems to indicate that variation of the velocity of the incident α particle may be accompanied by an enormous fluctuation in the probability of penetration when the energy approaches and enters the range of energy corresponding to one of the possible quasi discrete levels A systematic examination of thin films of various elements might disclose such a fluctuation, if the experimental difficulties can be overcome No resonance effect would be possible if we had discrete levels, indefinitely narrow, the absence of any genuine quantisation in the nucleus is due to the fact that the potential energy of the α or β particle must be taken as tending to zero when distant from the nucleus, in contrast to the method of Laue, it would seem, then, that the *Eigenwerte* of which he speaks (*Zeit f Phys*, **52**, pp 731 2) do not exist, but that all energies are possible (a continuous spectrum)

The transmission of particles through a simple potential barrier resembles transmission of light at a single reflecting surface, in that the coefficient falls off steadily with varying wave length But it is of course well known that the addition of a second reflecting surface (as in Fabry and Perot parallel plates) causes large fluctuations in the transmission, those wave lengths being favoured for which standing waves are possible, that is, when the thickness of the film is equal to one or more half wave lengths This provides a crude analogy to the case of the nuclear ψ functions, one half wave length for a free swift α particle being about $2\ 5 \times 10^{-13}$ cm Possibly the discovery by Rutherford and Chadwick of an energy giving minimum intensity of reflection of α rays at 135° (*Phil Mag*, **50**, p 900, 1925) was a resonance phenomenon

The application of the quantum mechanics may modify the interpretation, but seems to throw no light on the origin of the discrepancies between the results obtained at Cambridge and Vienna Although, for example, the argument in favour of a theoretical minimum range for the ejected H particles has lost its validity, since they may now escape through the potential barrier instead of having to fall through the entire repulsive field as had been previously argued by Chadwick (*Phil Mag*, **2**, pp 1073 4 1926), the experimental observation remains unaffected

The Average 'Forward' Momentum of Photoelectrons

IT is well known that the emission of photoelectrons by X rays is not symmetrically distributed about the plane normal to the rays, the photoelectrons possessing an average momentum in the forward direction I showed about a year ago (NATURE, Jan 28, 1928, p 134) that, contrary to general supposition, the average forward momentum μ, of a photoelectron is, according to experiment, not equal to the momentum $h\nu/c$ of an incident quantum, but is appreciably greater Sommerfeld in his recently published book, "Atombau und Spektrallinien, Wellenmechanischer Ergänzungsband" (1929), has treated the problem theoretically by the wave mechanics, and the purpose of the present note is to show the remarkable agreement of Sommerfeld's result with experiment

Sommerfeld (p 218) finds that the probability $P(\phi)\ d\phi$ of emission of a photoelectron at an angle between ϕ and $\phi + d\phi$ with the incident radiation is proportional to

$$\{1 + \tfrac{1}{2}\sqrt{(h\nu/mc^2)} \cos \phi\} \sin^3 \phi \ d\phi \qquad (1)$$

It follows from this that the average momentum of a photoelectron is

$$\mu_{theor} = 1\ 44(h\nu/c) \qquad (2)$$

The value found experimentally by Nuttall Barlow

and myself (*ibid.*, also *Proc. Roy. Soc.*, December, 1928) is

$$\mu_{expt} = 1.40(h\nu/c) \qquad (3)$$

If $\overline{\cos\phi}$ denotes the mean cosine of ϕ, θ the 'bipartition' angle (defined by $\int_0^\theta P(\phi)d\phi = \int_\theta^\pi P(\phi)d\phi$), and ρ the ratio of the forward to the backward emission, then according to (1)

$$2\,\overline{\cos\phi}/\beta = 1.44,\ 2\cos\theta/\beta = 1.80,$$
$$2(\rho - 1)/(\rho + 1)\beta = 2.70 \qquad (4)$$

β being the velocity of the photoelectron relative to that of light. The observed values of these quantities are 1.4, 1.8, and 2.6 respectively. Thus there is very good agreement with experiment whatever quantity is chosen as a measure of the asymmetry.

Formula (1) expresses the asymmetry to a first approximation, and is applicable only if $(h\nu/mc^2)$ and $(J/h\nu)$, where J is the binding energy of the electron, are small. These conditions are adequately satisfied in the cases investigated in the above experiments, namely, photoelectrons produced in nitrogen and oxygen by X-rays of wave-length 0.6 A.

Mention should be made of P. Auger's recent experiments in which he finds $\mu = 1.30(h\nu/c)$ for argon and $\lambda = 0.21$ A., and $\mu = 1.30(h\nu/c)$ for argon and $\lambda = 0.71$ A. (*Comptes rendus*, Dec. 10, 1928). These results and (3) show that $\mu/(h\nu/c)$, equals σ say, is approximately independent of λ and J as is required by (2). As mentioned in the previous paragraph, formula (1) represents the asymmetry only to a first approximation, and theoretically there should be a small variation of σ with λ and J which may account for the slightly smaller values of σ found by Auger. Auger's earlier observations (*Jour. d. Phys.*, February 1927) quoted by Sommerfeld correspond to $\sigma \simeq 0.9$, but this is refuted by his recent experiments.

Sommerfeld states that his calculated asymmetry is 9/5 times that expected on simple light quantum theory, but if we consider the mean momentum of the photoelectrons instead of the bipartition angle as Sommerfeld does, the ratio is $\frac{4}{5} \times \frac{9}{5} = 1.44$, as expressed by (2). The difference arises from different ways of regarding the simple light quantum theory and is unimportant.

E. J. WILLIAMS.

Cavendish Laboratory,
Cambridge, Mar. 6.

Anomalous Terms in the Spectrum of Doubly Ionised Lead

IN the course of an analysis of the spectrum of doubly ionised lead (Pb III), the results of which will shortly be published, some combinations of more than usual interest to spectroscopists were found to occur. These combinations involve the anomalous terms arising from the state of the doubly ionised atom of lead when both the two remaining valence electrons occupy $6p$ orbits. The terms to be expected for this state of the atom are 6^3P_{012}, $6^1\bar{D}_2$, and $6^1\bar{S}_0$.

As is well known, the rules for the transitions between states of an atom with two valence electrons are that $\Delta l_1 = 0$, $\Delta l_2 = \pm 1$, or $\Delta l_1 = \pm 1$, $\Delta l_2 = \pm 2$ where l_1 and l_2 are the azimuthal quantum numbers of the two electrons. Accordingly transitions from the $6p6p$ state to the following low lying states may be expected to occur: $6p6d$, $6p6s$, $6d6f$, $6s6f$. The second and fourth of these states lead to the important low lying terms 6^3P_{012}, 6^1P_1, 6^3F_{234}, and 6^1F_3. Applying the inner quantum number selection rules, we obtain between these terms and the anomalous 6^1D_2 term the following possible combinations: $6^3P_{12} - 6^1\bar{D}_2$, $6^1P_1 - 6^1\bar{D}_2$, $6^1\bar{D}_2 - 6^3F_{23}$, and $6^1\bar{D}_2 - 6^1F_3$.

All these combinations have been found. $\lambda\lambda$995.75, 1165.05 form the doublet $6^3P_{12} - 6^1\bar{D}_2$, and $\lambda\lambda$4004.16, 3925.23 the doublet $6^1\bar{D}_2 - 6^3F_{23}$, $\lambda\lambda$1439.42, 3832.83 are $6^1P_1 - 6^1\bar{D}_2$ and $6^1\bar{D}_2 - 6^1F_3$ respectively. The measures below 2000 A. are by Dr. R. J. Lang and are expressed in λI.A. vac., and those above 2000 A. are by myself and are expressed in λI.A. air. The source in each case was the vacuum spark.

It may be recalled that Sawyer (*Jour. Opt. Soc. America*, 13, p. 431, 1926) in the case of the arc spectrum of zinc, classified a doublet as arising from combinations between the 4^3P_{12} terms and an anomalous 4^1D_2 term. But so far as I am aware there have as yet been no cases recorded of the appearance of $F\bar{D}$ combinations for two valence electron systems. For this reason the FD lines mentioned above are of peculiar interest.

Of the three terms 6^3P_{012}, only $6^3\bar{P}_1$ has been found. This apparent absence of the 6^3P_{02} terms is in agreement with the known facts regarding the corresponding terms of Zn I, Ca I, and Hg I. The line λ2868.16 is also worthy of notice, as it appears to be $6^3P_1 - 6^3F_2$, a combination which is also to be expected. It is of course the only combination between the F terms and the $^3P_1$ term permitted by the inner quantum number transition rules. The $6^1\bar{S}_0$ term has not yet been determined. Unfortunately, only the combinations $6^3P_1 - 6^1\bar{S}_0$ and $6^1P_1 - 6^1\bar{S}_0$ are to be expected. There is at least one likely pair having the $6^3P_1 - 6^1P_1$ separation, but the absence of confirmatory evidence in the form of further combinations makes it difficult to come to a definite decision.

The first spark spectrum of thallium (Tl II), which is analogous to that of Pb III, has also been investigated and the $6^3P_{12} - 6^1D_2$ and $6^1P_1 - 6^1D_2$ lines have been found. The FD combinations would give rise to lines lying far in the infra-red, and consequently have not yet been identified.

Edmonton, Canada, Mar. 4.

Agricultural Education

THE leading article in NATURE of Mar. 9 on "Land and Industry" indicates an interesting possibility of dealing with the unquestionably important problem of establishing a 'land interest' among non-agricultural citizens. It might be worth while to consider the relation of agricultural education to this problem.

No one who has seriously considered the problem of national agricultural prosperity is likely to deny that the interest of the city and urban public is a primarily important factor. Nor is he likely to deny that those of us who are responsible for developing interest in agriculture have practically ignored the non-agriculturist. The activities of agricultural education have increased enormously during the last quarter of a century, but it seems to have been tacitly assumed throughout its developments that agricultural education is essentially and almost exclusively a provision for agriculturists, and that for the most part the proper people to exercise primary control over it are agriculturists and not educationists.

I have an ever increasing conviction (confirmed to no small extent by Mr. C. G. T. Morison's presidential address to the Agriculture Section of the British Association in 1927) that agricultural education can render a far greater service to the country if it will remove its delimitations and endeavour to attract

others than intended agriculturists If our university departments of agriculture would open their doors wider and offer courses for laymen as well as for agriculturists, and regard such courses as equally important, the ultimate development of a 'land interest' would surely be considerable If men and women who are destined to teach in our schools or to take a part in public affairs had the opportunity to read agriculture during a university course, the ultimate indirect effect on our national agriculture might be as great as the present direct effect of agricultural education

So far as its direct influence on farming practice is concerned, agricultural education is normally associated with some such phrase as "the application of science to farming" When, however, one considers the two great groups of factors which alone can create or alter an economic condition—scientific facts and philosophical outlook—one is left with more than a suspicion that the greater defect in our agriculture is not in science but in philosophy Great as is the scope for bringing more scientific knowledge to the farm, the limiting factor to-day is interest in farming and in the phenomena of the farm Without slackening its efforts to find scientific solutions of specific farm problems, agricultural education can greatly increase its service to the community by giving more attention to what after all is the essence of education, namely, the development and propagation of an interest in its subject matter

This suggestion in no way implies a criticism of the work of those agriculturists who, for the most part, control the administration of agricultural education in Great Britain The suggestion is rather that their work needs to be balanced by purely educational aspects of the teaching of agriculture in order that agricultural education may be developed with properly distributed emphasis and with greater usefulness to the community N M COMBER

The University, Leeds

The Occurrence of Ergosterol in Phytosterols

THE interest which has been aroused by the discovery that ergosterol is converted into vitamin D on irradiation has led us to consider its possible mode of formation in the vegetable kingdom

In this connexion some interesting facts arise from the recent work of Bonstedt (*Zeitschr für physiol Chem*, **176**, 269, 1928) on γ sitosterol, first detected by Anderson and Shriner in corn oil (*Jour Am Chem Soc*, **48**, 2976, 1926) This investigator has prepared a number of derivatives of this sterol, and a comparison of their physical properties with those of the isomeric derivatives in the ergosterol series reveals, as shown in the following table, a remarkable similarity

Formula	Substance	m p	$(\alpha)D$	Authority
$C_{27}H_{48}O$	γ-sitostanol	143 4°	+21°	Bonstedt (*loc cit*)
		144-5°	+18°	Anderson Shriner (*loc cit*)
	allo α ergostanol	144 5°	+16	Reindel and Walter, *Annalen* 460, 212 1928
$C_{29}H_{50}O_2$	γ-sitostanol acetate	144 5°	+12°	Bonstedt
	γ-sitostanol acetate	143°	+9°	Anderson, Shriner
	allo-α-ergostanol acetate	145	+6°	Reindel, Walter
$C_{27}H_{46}O$	γ-sitostanone	163°	+38°	Bonstedt
	allo α ergostanone	164°		Reindel, Walter
$C_{27}H_{48}$	γ-sitostane	87°	+20°	Bonstedt
	allo-α-ergostane	84 5°	+17°	Reindel, Walter

Reindel and Walter (*loc cit*) have shown that there is no depression of melting point on mixing γ sitostanol acetate with allo α ergostanol acetate, but infer from the difference in specific rotation that the two substances are not identical This contention we feel is open to question, for, as we have already pointed out (Heilbron, Morton, and Sexton, *Jour Chem Soc*, p 47, 1928), owing to the complex nature of the sterol molecule, the possibilities of racemisation at one or more of the asymmetric centres during the operations involved in their preparation cannot be excluded

The common and probably general association of dihydrositosterol with sitosterol in vegetable oils (*see* Bonstedt, *loc cit*, Anderson *et alia*, *Jour Amer Chem Soc*, **48**, 2972 *et seq*, 1926) suggests its genesis by a reduction process Similarly, as there is every reason to believe that ergosterol is also present in all phytosterols (Heilbron, Kamm, and Morton, *Biochem Jour*, **21**, 1279, 1927), we venture to suggest with all reserve that concurrent with its reduction to dihydrositosterol (sitostanol), oxidation of sitosterol (possibly γ sitosterol) to ergosterol occurs

The fact that neither of the two known tetrahydro ergosterols (ergostenols) is identical with the isomeric γ sitosterol is in no way remarkable It has been established that ergosterol contains an ethenoid linkage which resists hydrogenation under conditions which suffice to convert γ sitosterol into the fully saturated derivative, consequently, in the conversion of ergosterol to its tetrahydro derivative, the ethenoid linkage remaining must be in a different position from that present in γ sitosterol The suggested identity therefore only reveals itself in the fully saturated products

It is hoped that work which is now in progress in these laboratories may throw additional light on this important problem I M HEILBRON W A SEXTON

Transmutation of the Lighter Elements in Stars

THE formula given by Gamow (*Zeits f Phys*, **52**, p 512, 1928), for the probability that an α particle will penetrate the nucleus of an atom with which it collides, can be readily adapted to the case of proton impacts These have only half the charge of an α particle, and for the same energy twice the velocity, so that under conditions approaching thermodynamical equilibrium they have an enormously greater penetrating power We have investigated the possibility that in the interior of stars the process should actually occur with appreciable frequency, and we find that for the heaviest elements the probability is extremely small For the lightest, however, we obtain an average life varying roughly from 10 seconds for helium to 100 years for carbon in a fairly typical case The protons that are most effective, when their number is taken into account, are those with from three to four times the most probable velocity of the Maxwell distribution

We cannot well estimate the probability that a proton which has entered a nucleus will anchor itself there by radiating, but there are some indications that it may be high In that case there is an obvious possibility of gradually building somewhat heavier elements out of the lightest ones, this possibility is much improved if *electrons* can also penetrate the nucleus, but the calculation of this case has not yet proved practicable It seems, however, a plausible assumption We may then expect that the isotope Be^8 will be one of the products, this is probably unstable (it does not occur on the earth), and will then almost certainly break up into two helium nuclei, so that the supply of helium does not become exhausted, and the process

is limited only by the amount of hydrogen The theory obviously contains several uncertain hypotheses, but a calculation of the amount of energy that would be set free by the process gives quite the right order of magnitude In addition, the process fulfils the requirement of Eddington that its probability should increase very rapidly with the temperature at about 40 million degrees, and can also fulfil his requirement that it should contain a 'delay period' which is not dependent on temperature or pressure It thus seems possible that the stellar energy has a source in this method of element building which the wave mechanics has opened up to us But there are so many astro physical difficulties that we hesitate to express a definite opinion, more especially as it is difficult to see how the heaviest elements can be formed by this means at all

A full account of the investigation will appear shortly in the *Zeitschrift fur Physik* It would seem worth while to investigate the effect of fast protons on light elements in the laboratory, and experiments along these lines are contemplated

Internal Absorption of γ-rays

FOUR years ago (NATURE, 115, 13, 86, 1925), one of us estimated the internal absorption of the γ rays of radium D and the fraction of the atoms emitting γ rays Due to an oversight and, in the latter case, an arithmetical error, both estimations are incorrect They have recently been re calculated in the following manner

The relative ionisations produced by the β rays of radium E (in equilibrium with the radium D), and the soft and hard γ rays were measured in an electroscope, the walls of which consisted of paper coated with graphite and, after correction, were found to be 24,000, 40, and 2 6 respectively Assuming that the energy in a beam of X or γ rays is proportional to the total ionisa tion produced in air, the respective energies in the three types of rays were found to be proportional to 1500, 13, and 23 As the respective average energies of single rays are 350,000, 12,000, and 46,700 electron volts, we find that for the disintegration of 43 atoms of radium E or radium D, 11 atoms emit a soft γ ray (L radiation) and 5 atoms a hard γ ray No allow ance, however, has as yet been made for the fact that β rays are ejected by the hard γ rays from M and N levels (the consequent M and N radiations would not be observed in our experiments) Curtiss estimates that the intensity of the β rays ejected by the hard γ rays from the M and N levels is 70 per cent that from the L levels, so that, assuming the number of hard γ rays absorbed to be proportional to these intensities, 8 atoms emit M and N radiations

We arrive, therefore, at the following figures Out of 43 atoms disintegrating, 24 atoms emit γ rays Of these 24 γ rays, 19 suffer internal absorption It seems probable that, in the case of all substances, only a fraction of the atoms emit γ rays after a β ray dis integration This should be taken into account in estimating times of emission of γ rays

A further set of experiments was carried out to determine if there were any β rays emitted from radium E with energy of the order 2,000,000 electron volts The method used may be of interest and is given below An electroscope was placed on top of the poles of an electromagnet, which produced an average field of 1250 gauss The active material was 10 cm below the bottom of the electroscope Sufficient material was placed beneath the electroscope to cut off secondary β rays produced by γ rays, and, directly over the active material, absorption sheets which cut down β rays of energy 2,000,000 volts until the issuing rays had a value of $H R < 6000$ Such rays would be deflected from the electroscope by the magnetic field No difference was found between the electroscope readings with and without magnetic fields Allowing for the difficulty of measuring small differences, we estimate that less than one atom in 25,000 emits a β ray of energy 2,000,000 volts, and possibly none at all

Diœcism in *Ranunculus acris*

MR R O WHYTE's letter in NATURE of Mar 16, p 413 on the cytological aspect of the hitherto little noticed peculiar form of the common acrid buttercup, stimulates me to make some general remarks respect ing it

I first made its acquaintance in the spring of 1923 near my home in Cumberland, and sent specimens to the Linnean Society of London They were exhibited at the meeting held on June 21 (*Proc Linn Soc*, p 50, 1923) Through lack of time, I believe, they were not discussed I then approached a leading authority on the British flora, Dr Claridge Druce, who kindly replied to the effect that this form was strange to him He incorporated it in his "Plant Notes" for 1923 (*Report*, Bot Exchange Club, p 24, 1923), with an extract from my letter, naming it *Ranunculus acris* L var, sub var, or forma *minutiflorus*, Druce

Finding that Mr Marsden Jones was working on the genetics of the genus *Ranunculus* I sent specimens to him, and he was not long in reporting to me the occur rence of the same in his own neighbourhood, Potterne, Wilts I am glad to see that he has not only taken up the genetics of it, but also has prevailed upon Mr Whyte to work out the cytological side—a piece of research which promises to shed light on the origin of unisexual from hermaphrodite flowers

It is curious that this 'female' form of *Ranunculus acris* has not excited attention previously None of the British floras consulted refer to it Since it came under my notice for the first time in 1923, I have seen it every subsequent season in fair abundance in my own neighbourhood Apparently it is a general associate of the ordinary form of this buttercup What exactly is its significance in the bionomics of the species it is difficult to say One might hazard the view, tempting but not altogether probable, that *Ranunculus acris* is in the incipient stage from her maphroditism to gynodiœcism

Though no exact calculation as to the frequency of this 'female' form among the ordinary type in my neighbourhood has been made, one per cent might be a possible estimate, though of the extreme cases with stamens as mere rudiments this might be a consider able overstatement The extreme form is very notice able on account of the much smaller size of the petals Moving such 'female' plants to the garden has not changed the size or character of the flowers in subse quent seasons, so that the reduced nature of the corolla and the abortion of the stamens are apparently not due to poverty of soil or other adverse conditions No difference in vegetative characters can be detected between the ordinary and the 'female' plants The latter appear just as vigorous in growth

Excitation of Mercury Vapour by the Resonance Line

IN supplement to my letter in NATURE of Mar 30, p 488, under the above title, I have now made a series of experiments, starting with mercury resonance radiation under typical conditions at room temperature As the temperature of the mercury is progressively raised, and a rapid stream of vapour is generated, the secondary source, originally symmetrical on either side of the primary beam, begins gradually to elongate on the down stream side, until finally it is wholly on this side, being traceable for a distance of about 3 cm down stream

Although this result is unexpected, and contrary to prevailing views, the photographic evidence is very clear I hope to publish the photographs in due course RAYLEIGH

Invisible Oxide Films on Metals

THE well known work of Evans on the passivity of metals has led to the conclusion that oxidation can occur at room temperature on copper and iron, giving a film which is too thin to show interference colours In his lecture to the American Institute of Mining and Metallurgical Engineers (1929) he has remarked that it is logical to suppose that the oxide film has a real existence before any interference tints are shown Evans quotes the work of Freundlich, Patscheke, and Zocher (*Z physikal Chem*, 128, 321, 1927), who have made pure metallic iron mirrors from iron carbonyl They find distinct changes in the reflecting power when air is admitted, showing the formation of oxide films of the order of 10^{-7} cm in thickness

Muller and Koenigsberger (*Phys Zeit*, vol 5, p 413, 1904) have found that there is little difference in the reflecting powers of iron in the active and passive states In my experiments at temperatures at which the iron interference colours are formed very slowly, there is distinct evidence from the reflecting power of surfaces that there is an oxide film present before there is any evidence of interference colours visible to the eye (cf *Proc Roy Soc*, A, vol 117, p 376, 1928)

In the early stages of oxidation the reflecting power of iron, nickel, and copper becomes somewhat smaller over the whole range of the spectrum, but slightly more so at the violet end of the spectrum than in the red, showing the existence of an absorption maximum far away in the ultra violet region

During the study of the spectrophotometry of the growth of sulphide films on metallic copper, evidence was obtained strongly supporting Evans's conclusions of the formation of an oxide film at room temperatures If reduced copper be attacked with a mixture of one volume of hydrogen sulphide and five volumes of air, two complete colour sequences are produced in a few minutes, if, however, the copper surface be left exposed to air for some hours, and then hydrogen sulphide and air admitted, the interference colours are developed very slowly indeed Only one colour sequence could be observed during a whole day's exposure In addition there was a general dulling of the colours so formed

Heating the metal to 300° C in a nitrogen vacuum of 10^{-5} mm did not remove the film Hence there is clear evidence in support of the conclusion that a thin film of oxide is formed on copper merely on exposure to air at ordinary temperatures

Solutions and Heat Engines

THE nature of osmotic pressure is a matter of such great importance both to chemists and to physiologists that I must again crave space to reply to the remarks of the reviewer in NATURE of Mar 23, p 445

In justification of his, or van 't Hoff's, account of osmotic pressure, he points to the description in my book of what would happen if a mixture of two gases at atmospheric pressure in a rigid chamber was separated by a rigid septum, permeable by only one of the two gases, from pure gas of the same kind as could permeate, and at the initial pressure of the mixture The pure gas would pass into the mixture, the pressure of which would rise until the pressure of the penetrating gas was the same in the mixture as outside of it The gas which penetrates corresponds to the solvent in a solution, and the non penetrating gas to the solute, while the extra pressure developed in the mixture might be held to correspond to osmotic pressure May I point out, however, that this extra pressure is due to solvent and not to solute molecules There is thus in the phenomena no way of escape from the dilemma for van 't Hoff's theory which I indicated in my letter Van 't Hoff's assumption that osmotic pressure is due to extra bombardment pressure of solute molecules is both unintelligible physically and inconsistent with the facts as revealed by the experiments of Morse and Lord Berkeley

The algebraical statement on page 25 of my book, to which the reviewer objects, is, I maintain, perfectly correct, and I am well content to leave the judgment as to its correctness with readers of the book

J S HALDANE

Cherwell, Oxford, Mar 23

I WILL add only one short note to what I have said Consider two cases (1) One atmosphere of hydrogen on each side of the septum and no nitrogen The osmotic pressure is zero (2) Two atmospheres of nitrogen inside the chamber and again one atmosphere of hydrogen on each side This also is an equilibrium case and the osmotic pressure is TWO atmospheres By what wild theory is this attributed to the ONE atmosphere of hydrogen ! THE REVIEWER

Science and Mathematics

THE sentence italicised in the following from a work published in 1877, seems to have anticipated the views of relativists by half a century "Any kabalist well acquainted with the Pythagorean system of numerals and geometry can demonstrate that the metaphysical views of Plato were based upon the strictest mathematical principles 'True mathematics,' says the *Magicon*, 'is something with which all higher sciences are connected, common mathematics is but a deceitful phantasmagoria whose much praised infallibility only arises from this—that materials, conditions, and references are made its foundation' As long as exact science confines its observations to physical conditions and proceeds by the Aristotelian method it certainly cannot fail But, ***notwithstanding that the world of matter is boundless for us, it still is finite***, and thus materialism will turn forever in this vitiated circle, unable to soar higher than the circumference will permit The cosmological theory of numerals which Pythagoras learned from the Egyptian hierophants is alone able to reconcile the two units, 'matter' and 'spirit,' and cause each to demonstrate the other mathematically" —"Isis Unveiled," i 7 W W L

Evolution in its Course

ONE of the most persistent plaints of the anti evolutionist is that the biologist has failed to demonstrate to the satisfaction of the unbeliever the actual occurrence of evolution in the present day world The criticism is difficult to meet, for, apart from the blind eye which the critic is apt to turn to the well meaning efforts of the biologist, evolution is a slow process not readily to be caught in its stride Even amongst biologists themselves there has been a tendency in recent years to look askance at the work of the systematist, and to lean upon the experiments of the laboratory as the only sure test of biological processes

It is well to be reminded, therefore, that the last decade has seen a great advance in the technique of the systematist, and that the advance has afforded new ground for the examination of the problem of evolution in natural conditions In the old days an account of the bird life of a limited area in California would have meant little more than the bare records of a local list of the bird inhabitants, but, under the new analysis, Mr Joseph Grinnell's " Distributional Summation of the Ornithology of Lower California " (*Univ California Pub Zool*, vol 32, No 1, 1928, pp 1 300) becomes a plea for the recognition of evolution in its course

Two factors have made for this progress in method The first is the attention given to the discernment of minute differences in form, and it is sufficient answer to those who cavil at the difficulties of the determination of sub species, that in these barely recognisable differences lie the critical, formative stages, which may lead to the development of easily distinguished species The second factor lies in the attempt to associate these minute differences of sub species with the peculiar conditions of environment in which each is situated, in an endeavour to discover something of the causes and essential conditions of the differentiation

The general results of the analysis of the bird life of California show, then, the progress of evolution in Nature, as closely as the examination of static conditions can be expected to interpret a continuous process They do not reveal anything that is particularly novel or unexpected, but the fact that they are based upon an intensity of examination and detail of comparison such as was unavailable to Darwin or Wallace, lends them new weight and authority

In the first place, there is evidence of gradual differentiation Among the numerous races of Californian birds, examples can be selected showing practically every appreciable stage in differentiation, from neighbouring stocks showing departures from a type so slight that they can be appreciated only when a long series of individuals is averaged, to full-blooded species, sharply distinct, no longer crossing with related species, judging from the absence of wild hybrids

In the second place, the differentiation, that is, the variational move towards species, is not everywhere a uniform process The inequality may be associated with several definite characters of the environment Thus, in many of the groups of wide distribution, the amount of difference shown by the geographical races varies directly with the degree of spatial separation Take the clear case of the group including the California linnet (*Carpodacus*) The group extends over the mainland, a distance north and south of some eight hundred miles, and in that space has three recognisable subspecies But on Los Coronados Islands, only seven miles off shore, there is another race, appreciably but not constantly or conspicuously different Forty miles from the nearest mainland, on the San Benito Islands, there are greater and fairly constant differences from the birds of the mainland, and on Guadalupe Island, 135 miles away, the differences are so great and constant that the form there is designated a full species

The differences themselves are significant The Guadalupe birds are distinguished by their larger size, longer legs, relatively shorter wings, and shorter keel of sternum — indications of a loss of wing power, which suggest a step towards the flightlessness of some other birds on remote Pacific islands

Even a slight water barrier may be influential as an effective form of isolation, preventing free interbreeding of birds from neighbouring places Although there are no apparent barriers in the whole extent of the mainland of lower California, long distance has had the same isolating effect, allowing differentiation in remote stocks despite commingling over adjacent territory

Other cases of the influence of isolation, such as that shown by the spotted towhee (*Pipilo maculatus*), could be cited, they illustrate the fact that closely similar races in a series are not situated " within the same differentiation area, nor yet in remote differentiation areas, but in separate and adjacent differentiation areas "

In the third place, it becomes clear that environment may have an effect which, no matter that the subjects of its influence are different, results in a remarkably similar set of results A very peculiar climatic condition exists between the crest of the Sierra San Pedro Mártir and the Pacific, where a region of meagre rainfall has a high atmospheric humidity—a humid desert Various birds in this region, as different as flycatchers, finches, and woodpeckers, show similar modifications, especially marked in deeper coloration, certain proportions of wing and tail, lesser size of bill, and so on Subjection of very different stocks to the same peculiar set of critically important conditions has brought parallel modifications in certain functions and structures

This suggests that the inherited variations have not been random, but have been directed So far so good, but the author goes on to say that subspecific characters are therefore to be regarded, either intrinsically in themselves or in their linkages, as of *worthy* sorts in the racial struggle for existence —not, ordinarily, indifferent or useless ones Here he seems to travel in advance of his facts, for it has

yet to be shown that the common characters which have been induced by a peculiar environment in so many different kinds of birds can have an equal survival value to each of these birds of habits so different On the facts put thus, the safer assumption would seem to be that similar conditions induce a similar organic reaction irrespective of 'worthiness' or 'unworthiness'

After all, unworthiness in the evolutionary sense is not likely to survive in hard competition with worthiness, and Mr Grinnell finally reaches a Darwinian conclusion "The accumulating evidence of the field naturalist is bringing conviction that the incipient species in nature, the subspecies, owes its origin to a process, on a vast scale, of trial, discard, and preservation, of individuals, and of groups of individuals comprising populations, which populations from generation to generation are thereby rendered more nearly adjusted to such environments as they can endure at all But environments themselves never stabilize, they are changing, proliferating, evolving continually A balanced state of perfect adaptation of the organism can never be attained, but only continually approached, such approach being forced, under penalty of extinction"

J R

Physical Foundations of Chemical Theory

NO task is more difficult for the chemist of the present day than that of trying to keep abreast with those advances in atomic physics which affect him so closely that he cannot ignore (even if he cannot hope fully to understand) them Sidgwick's book on "The Electronic Theory of Valency," which was reviewed at length in these columns last year (April 7, 1928, vol 121, p 527), provided a partial solution of the problem from the chemist's point of view, but the brief monograph of Lessheim and Samuel referred to below [1] may be regarded as a complementary contribution of unrivalled value from the physical side The professional spectroscopist does not often realise how difficult his subject can be made for the lay reader, and it is a common experience, even when reading books or lectures of a semi popular character, to be pulled up short by technical or controversial details of which no explanation is given or attempted

In the more leisurely days of the past, there was usually ample time for one fundamental idea to be grasped before attention was distracted by the next new development Progress was then made by the orderly passing of the ball from one three quarter back to another, until it was safely placed behind the goal, and in due course 'converted' from speculation or hypothesis to theory Now, however, the ball progresses amid the confusion of a wild 'forward' rush, in which the casual onlooker can only occasionally get a glimpse of the ball, and has but little chance to observe the effects of individual play, whilst even the professional reporter is in danger of overlooking essential points in the game Thus, whereas Bohr's 'principal quantum number' n had a sufficient start to secure universal acceptance, and has retained its strictly integral character, it has been followed in the works of subsequent authors by a trail of subsidiary numbers, which are in open competition with one another, and (to add to the confusion) appear at some stage to have undergone a process of 'disintegration' whereby integral quanta have been resolved into proper fractions

The difficulties arising from such causes as these are in large measure removed by the careful and concise exposition of Messrs Lessheim and Samuel, and it is a high compliment to their skill that we can claim to have been able to understand and to make use of the major portion of their monograph It was, indeed, only on reaching the tenth section of the book that it became necessary to add a marginal comment, "I cannot follow this," and to call in the help of a professional physicist to explain in fuller detail the complex behaviour of systems with several outer electrons The elaborate spectroscopic analysis of sections 12 and 13 was also too complicated to be understood at one reading, but it would be difficult to praise too highly the way in which the spectroscopic evidence is used in order to provide a sure foundation for definite chemical deductions, and it is one of the conspicuous merits of the book that this evidence is set out in such a convincing way, that its validity is no longer open to question even by the most extreme type of 'sceptical Chymist'

Much of the charm of the quantum theory of the present day arises from the introduction, by Goudsmit and Uhlenbeck in 1925, of the conception of the spinning electron This conception has, indeed, done more than anything else to bring order out of the chaos of subsidiary quantum numbers, and thus to restore to Bohr's theory some semblance of the simple and logical character which it possessed in 1913 From the chemical point of view, the principal merits of this early quantum theory was the provision of a logical basis for the valency theories of Kossel and Lewis, since it indicated the existence of groups of electrons with identical 'principal quantum numbers' $n = 1, 2, 3, 4, 5$, etc, corresponding with the K, L, M, N, O, etc, levels of the X ray spectra of the elements In this way it explained the inertness of the noble gases, and the ionisation of adjacent elements such as the halogens and the alkali metals, as depending on the exceptional stability of certain completed groups of electrons Since, however, the theory gave no clue to the number of electrons in each quantum group, these numbers must logically have followed the Rydberg series, with 2, 8, 8, 18, 18, and 32 electrons in successive levels, corresponding with the number of 'cells' which Langmuir postulated in successive layers or 'shells' of his static atomic model

[1] Die Valenzzahl und ihre Beziehungen zum Bau der Atome Von Hans Lessheim und Rudolf Samuel. (Fortschritte der Chemie, Physik und physikalische Chemie, herausgegeben von A Eucken, Band 19, Heft 3) Pp 98 (Berlin Gebrüder Borntraeger, 1927) 6 40 gold marks.

Two years later, in 1915, Sommerfeld found it necessary to introduce a second ('subsidiary' or 'azimuthal') quantum number k, in order to explain the fine structure of the hydrogen and helium spectra This 'subsidiary' quantum number immediately assumed a dominant position in spectroscopy, where series of spectroscopic terms for which $k=1, 2, 3, 4$, were distinguished by the capital letters S, P, D, F, corresponding with the initial letters of the 'sharp,' 'principal,' 'diffuse,' and 'fundamental' series of spectral lines with which the terms are associated It is unfortunate for the lay reader of spectroscopic literature that the fascinating explanation which Sommerfeld gave of the fine structure of hydrogen, as depending on the varying mass of electrons moving with varying velocity in elliptical orbits of different eccentricities, has now been abandoned in favour of a fine structure depending on a third (instead of on the second) quantum number, but the classification of Bohr's 'groups' of electrons into 'sub groups,' under the headings $n_k = 1_1 2_1 2_2 3_1 3_2 3_3$, etc, was nevertheless an advance of permanent value In particular, it was these sub groups which enabled Bohr in 1921 to develop his well known classification of the elements, in which the inertness of the noble gases is no longer attributed to the completion of the main groups with principal quantum number $n=1, 2, 3, 4$, etc, but to the completion only of successive n_1 and n_2 sub groups, as in the table below

X ray level	K	L	M	N	O	P
Quantum No	1_1	$\underbrace{2_1 2_2}$	$\underbrace{3_1 3_2} 3_3$	$\underbrace{4_1 4_2} 4_3 4_4$	$\underbrace{5_1 5_2} 5_3$	$\underbrace{6_1 6_2}$
He = 2 =	2					
Ne = 10 =	2	+ 8				
A = 18 =	2	+ 8	+ $\underbrace{8}$			
Kr = 36 =	2	+ 8	+ 18	+ $\underbrace{8}$		
X = 54 –	2	+ 8	+ 18	+ $\underbrace{18}$	+ $\underbrace{8}$	
Rn = 86 =	2	+ 8	+ 18	+ 32	+ 18	+ 8

This well known system of classification assigns an outer shell of 8 electrons to each of the noble gases, and explains the old 'law of octaves' by the repetition which results from building up this outer octet in one level after another It then proceeds to account for the properties of the transition elements of the first and second long periods as depending on a subsequent expansion of the M and N octets into shells of 18 electrons The final expansion of the N octet to a shell of 32 electrons (at a stage when the O and P levels are already partially filled) then provides a natural explanation of the still slower gradation of properties in the elements of the rare earth group

Since the number of similarly placed electrons was still undetermined, Bohr adopted the simple plan of distributing them equally amongst the sub-groups of a given level The N-level was therefore supposed to contain $4+4$ electrons in krypton, $6+6+6$ in xenon, and $8+8+8+8$ in radon It is, however, rather illogical to postulate that a condition of maximum stability exists in a sub group when occupied by 4 *or* 6 *or* 8 electrons Stoner therefore suggested in 1924 that the various sub groups should be filled up completely one after another, and then remain full to the end of the chapter It then follows logically that the sub groups for which $k=1, 2, 3, 4$, etc, must contain 2, 6, 10, 14, etc, or in general $2(2k-1)$ electrons, whatever may be the value of the principal quantum number n The close similarity between the members of the various natural families of elements was then explained by the identical development of successive sub groups differing only in their 'principal' quantum numbers Thus the alkalis all contain *one* electron in an n_1 sub group, whilst the alkaline earths contain a complete sub group of *two* electrons In the same way carbon and its homologues contain *two* electrons in an n_2 sub group, in addition to the two electrons in the n_1 sub group, whilst the inert gases contain a complete sub group of *six* n_2 electrons

In the periodic classifications of Bohr and of Stoner, the maximum number of sub groups in a group is fixed by the fact that k may have any integral value between 1 and n The number of sub groups is therefore equal to the principal quantum number n, and has the value 1, 2, 3, 4, 5, in the K, L, M, N, O levels Coster found, however, in 1921, that the X ray absorption spectra of the elements have a fine structure like that of hydrogen or helium, the number of components in the K, L, M, N, O, P levels being expressed by the series 1, 3, 5, 7, (5), (3), instead of the series 1, 2, 3, 4, 5, 6 In order to explain this result, he introduced a third quantum number in the form $n_{k_1k_2}$, where k is now written as k_1 and may be any integer between 1 and n as before, whilst k_2 may be either equal to k_1 or 1 unit less The sub groups of the preceding classification are thus divided up into 'grouplets' corresponding with a series of triple quantum numbers as follows 1_{11}, 2_{11}, 2_{21}, 2_{22} 3_{11}, 3_{21}, 3_{22}, 3_{32}, 3_{33}, etc This system gives the required series of 1, 3, 5, 7 components in the K, L, M, N levels, as required by the X ray spectra, and we may then suppose that, as in the optical spectra, the O and P levels are only partially filled

A third quantum number had already been introduced by Sommerfeld in 1920 in order to account for the composite character or 'multiplicity' of lines, such as the sodium doublet, which could not be explained by means of the first two quantum numbers Sommerfeld's 'inner' quantum number j can have integral values when there are *two* valency electrons which can move from orbit to orbit during the absorption or emission of light by the atom, as in the alkaline earths, but when there is only *one* of these electrons it becomes a half integer, and its value is given by the relation $j=k_2-\frac{1}{2}$ This third quantum number is evidently magnetic in origin, since it also explains the multiplicity which is developed when spectral lines are emitted in a strong magnetic field as observed by Zeeman in 1896 Under these conditions a single line is resolved into $2j+1$ components, where j is the inner quantum number

Thus if j is an integer, the lines break up into an odd number of components, but into an even number if j has a half-integral value

The significance of the third quantum number becomes clear only when a quantised spin is given to the electron The magnetic moment s of the spinning electron can then be either positive or negative, but, since there is no intermediate resting state, only a single quantum separates the two states For the sake of symmetry, therefore, these states are written $s = \pm\frac{1}{2}$ for each electron, and we have at once a plausible explanation of those half quantum numbers which have so often caused the sceptical to scoff The total magnetic moment j of a planetary electron is then made up of two parts, the magnetic moment of the orbit l and of the spin s, so that $j = l \pm s$, since the moments may either work together or oppose one another The magnetic moment l of the orbit is a function of the second or 'subsidiary' quantum number k, and is given by the simple relation $l = k - 1$ Thus if $k = 1$ (as in the S terms of a spectroscopic series) $l = 0$, and since $j = l + s$ cannot be negative, the only possible value of the 'inner' quantum number when $s = \pm\frac{1}{2}$ is $j = \frac{1}{2}$ If, however, $k = 2$ (as in the P terms of a spectroscopic series), then $l = 1$, and $j = l + s$ can have the *two* valves $j = \frac{1}{2}$ or $j = \frac{3}{2}$ An electron fall from a 2_2 to a 1_1 orbit can thus give rise to the yellow doublet of sodium, since the falling electron may be spinning either in the same sense as its revolution in the orbit or in the opposite sense

The introduction of the second quantum number had the effect of breaking up the main groups of 2, 8, 18, 32 electrons into sub groups of 2, 2 + 6, 2 + 6 + 10, and 2 + 6 + 10 + 14 electrons The third quantum number has the effect of breaking up these sub groups into tiny grouplets containing small even numbers of electrons Thus Bohr's big group of 32 N electrons is resolved into the following grouplets

$$\begin{array}{ccccccc} 4_{11} & 4_{21} & 4_{22} & 4_{32} & 4_{33} & 4_{43} & 4_{44} \\ 2 & 2 & 4 & 4 & 6 & 6 & 8, \end{array}$$

and the 54 electrons of xenon are now distributed amongst 17 grouplets as follows 2, 2 + 2 + 4, 2 + 2 + 4 + 4 + 6, 2 + 2 + 4 + 4 + 6, 2 + 2 + 4 This has the effect of emphasising more strongly than ever the significance of the duplet or pair of electrons, since each completed grouplet is magnetically inert, but the octet is relegated to a subsidiary position as a mere summation of the first three grouplets in a group which contains $2n - 1$ of these tiny clusters

In order to complete this process of resolution, we must now proceed to consider the fourth quantum number m, which represents the various settings of the atom in an external magnetic field This fourth quantum number changes by one unit at a time from $+j$ to $-j$, and may therefore be either integral or half integral The number of settings for a given value of j is given by the formula $2j + 1$, thus if $j = \frac{1}{2}$, $m = \pm\frac{1}{2}$ and has *two* values, if $j = 1$, $m = -1, 0, +1$ and has *three* values, whilst if $j = \frac{3}{2}$, $m = -\frac{3}{2}, -\frac{1}{2}, +\frac{1}{2}, +\frac{3}{2}$ and has *four* values The total number of settings of the *four* quantum numbers n, l, j, and m is then found to agree exactly with the maximum number of electrons that can be collected in groups, sub groups, and grouplets round the nucleus We are therefore at last in a position to appreciate Pauli's 'exclusion rule,' according to which no two electrons in an atom can have the same four quantum numbers, n, l, j, and m A sample of the table which expresses this rule is reproduced below

				Number of Settings.			
$n = 1, 2, 3, 4, 5, 6$	$l = 0$	$j = \frac{1}{2}$	$m = -\frac{1}{2} + \frac{1}{2}$	2	2	8	
$n = 2, 3, 4, 5, 6$	$l = 1$	$j = \frac{1}{2}$	$m = -\frac{1}{2} + \frac{1}{2}$	2	6		
		$j = \frac{3}{2}$	$m = -\frac{3}{2} + \frac{1}{2} + \frac{1}{2} + \frac{3}{2}$	4			18
$n = 3, 4, 5, 6$	$l = 2$	$j = \frac{3}{2}$	$m = -\frac{3}{2} - \frac{1}{2} + \frac{1}{2} + \frac{3}{2}$	4	10		
		$j = \frac{5}{2}$	$m = -\frac{5}{2} - \frac{3}{2} - \frac{1}{2} + \frac{1}{2} + \frac{3}{2} + \frac{5}{2}$	6			32
$n = 4, 5, 6$	$l = 3$	$j = \frac{5}{2}$	$m = -\frac{5}{2} - \frac{3}{2} - \frac{1}{2} + \frac{1}{2} + \frac{3}{2} + \frac{5}{2}$	6	14		
		$j = \frac{7}{2}$	$m = -\frac{7}{2} - \frac{5}{2} - \frac{3}{2} - \frac{1}{2} + \frac{1}{2} + \frac{3}{2} + \frac{5}{2} + \frac{7}{2}$	8			

This table gives a picture of the periodic classification from which all individuality is excluded, since exactly the same sequence recurs when $n = 2, 3, 4$, etc It thus represents one of the main characteristics of the elements perfectly, namely, the recurrence of types such as the halogens, noble gases, and alkalis at appropriate intervals, but in practice the elements of a given family are far from uniform in their behaviour, so that even the formal valencies vary erratically in a family such as copper, silver, gold It is therefore satisfactory to find that the spectroscopic evidence, when examined in detail, gives similar indications of more complex developments Thus it is found experimentally that, in the elements of the *first* transition series, the grouplet 4_{11} of the N level is occupied by *two* electrons (except in chromium and copper) so that all these elements readily form bivalent ions In the same way, the first two elements (yttrium, zirconium) of the *second* transition series have *two* electrons in the 5_{11} grouplet of the O level, but at this stage there is an abrupt change, since the following elements (niobium, *et seq*) have only *one* electron in the 5_{11} grouplet, and palladium actually has *none* In the next group of transition elements tungsten appears to have *two* electrons in the 6_{11} grouplet, but no conclusion can be drawn in reference to the other elements of this transition series, since the relevant spectroscopic data are not yet available These unforeseen 'anomalies' are of peculiar interest, since they show that the individuality of the elements, which makes inorganic chemistry appear so much less systematic than organic chemistry, is manifested also in their spectroscopic behaviour, which may therefore be expected to provide a clue to the common origin of these physical and chemical anomalies in the electronic configuration of the atom

A particularly interesting comparison can be made between nickel, palladium, and platinum The structure of these three elements could be represented most easily by assigning an outer

shell of 18 electrons to each metal, as in the scheme

$$
\begin{array}{l}
\quad\quad\ K \quad L \quad M \quad N \quad O \\
\mathrm{Ni} = 2 + 8 + 18 \qquad\qquad = 28 \\
\mathrm{Pd} = 2 + 8 + 18 + 18 \qquad = 46 \\
\mathrm{Pt} = 2 + 8 + 18 + 32 + 18 = 78
\end{array}
$$

This structure is correct in the case of palladium, which appears to contain a series of complete grouplets, since it is only feebly paramagnetic and gives a spectrum with some of the characteristics of a noble gas, but it is no longer true for nickel and platinum, the spectra of which are more like those of the alkaline earths, so that their structure may be represented more efficiently by the schemes $2+8+16+2$ and $2+8+18+32+16+2$

The spectroscopic data thus explain the typical bivalency of nickel and its resemblance to the bivalent transition elements with which it is associated, but they do not throw much light on the chemistry of palladium and platinum, since these two metals do not show any analogous contrast in their chemical behaviour If, however, we consider the coinage metals of the succeeding family, Cu = 29, Ag = 47, Au = 79, the value of the spectroscopic data is at once seen Thus, since palladium contains only completed groups or sub groups of electrons, and has therefore a very stable electronic configuration, it is natural that silver should exhibit the simple spectrum and rigid univalency of an alkali metal, as expressed in the scheme $\mathrm{Ag} = 2+8+18+18+1$ In the case of copper, the univalency of the element in its cuprous salts is similarly expressed in the scheme $\mathrm{Cu} = 2+8+18+1$ In strict conformity with this scheme, the cuprous ion, $\mathrm{Cu}^{+} = 2+8+18$, which has three levels completely filled, is diamagnetic, but the cupric ion, which possesses an incomplete shell $\mathrm{Cu}^{++} = 2+8+17$ is paramagnetic Since copper is usually bivalent, we might expect to find spectroscopic evidence of a configuration $\mathrm{Cu} = 2+8+17+2$, corresponding with $\mathrm{Ni} = 2+8+16+2$, with two electrons in the 4_{11} grouplet, but this does not appear to have been observed On the contrary, the presence of quadruplet groups in the spectrum of copper indicates the presence of *three* unpaired electrons round the central nucleus This brings the metal into line with nickel, but in a different way, since the stable core of electrons has $2+8+16$ electrons in each case, but it is not in accord with the chemical properties of the element, which may be univalent but is never tervalent

The univalency of gold finds expression in the configurations

$$\mathrm{Au} = 2+8+18+32+18+1,$$
$$\mathrm{Au}^{+} = 2+8+18+32+18,$$

which show the presence of *one* easily detached electron in the *P* level Its tervalency can be deduced from the analogy between the spectra of platinum and those of the alkaline earths with *two* easily detached electrons, since this indicates the existence of a stable core with 16 *O* electrons as in the scheme

$$\mathrm{Au}^{+++} = 2+8+18+32+16,$$
$$\text{compare } \mathrm{Pt} = 2+8+18+32+16+2$$

In this connexion, the univalency of thallium, which finds expression in the scheme $\mathrm{Tl}^{+} = 2+8+18+32+18+2$, is of interest, since it provides further evidence of the stability of the outer sub group of two 6_1 electrons which has already been deduced from the spectroscopic data for platinum

The introduction of sub groups of elements has the interesting effect of removing carbon and silicon from the central position which they have long occupied in the minds of chemists as the middle

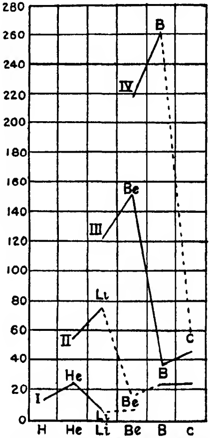

FIG 1 —Diagram showing the ionisation potentials required to remove 1 2 3, or 4 electrons from the first six elements.

members of the two short periods of elements From the spectroscopist's point of view, however, a sub group 2_1 or 3_1 has been completed at beryllium and magnesium, and it only remains to build up the six electrons of the 2_2 or 3_2 sub groups in order to give the configuration of a noble gas In this process, nitrogen and phosphorus usurp the median positions, and this is revealed by an unexpected symmetry in the spectroscopic terms of the elements on either side Thus the spectrum of magnesium shows some resemblance to that of argon, whilst aluminium and chlorine, and silicon and sulphur form similar pairs, in which the electrons which are present in one element are represented by gaps in the other A similar symmetry is seen on either side of manganese in the transition elements of the first long period,

where the 3_3 sub group is being filled up, but in this case the symmetry is marred by the fact that chromium and copper have only *one* outer electron instead of two in the 4_{11} grouplet In the elements of the rare earths, where the 4_4 sub-group is being filled with fourteen electrons, gadolinium occupies a central position in a series of fifteen elements ranging from lanthanum to cassiopeium, but in this case the central element is characterised by an extraordinary maximum of multiplicity, $r = 17$, which is far in excess of the previous maximum values, namely, $r = 4$ for nitrogen and phosphorus, and $r = 6$ for manganese, or $r = 7$ for the anomalous spectrum of chromium

The culminating feature of Messrs Lessheim and Samuel's monograph, in our experience, is found in a diagram of ionisation potentials (Fig 1), which provides the most convincing proof of the real existence of electron groups The minima at Li^+, Be^{++}, B^{+++}, and C^{++++} show how easy it is to remove the whole of the electrons from the L level in lithium, beryllium, boron, and carbon, but, on attempting to remove one more electron, an immense resistance is at once encountered to the disintegration of the still complete K shell, and the ionisation potential leaps up to a maximum When once this shell is broken, however, only a feeble resistance is offered to its complete removal Thus the two L electrons can be removed from an atom of beryllium by two increments of about 8 and 7 volts, but the removal of the two K electrons requires the successive addition of 138 and 46 volts to the previous total of about 15 volts The most striking feature of these numbers is the drop of nearly 100 volts in the extra work that is required to strip the nucleus bare by the removal of one more electron when once the K shell has been broken Even the tiny duplet of the 2_{11} grouplet appears, however, to put up an appreciable resistance to disruption, since rather less extra work is required to remove an electron from the ion Be^+ than from the neutral atom Be Facts such as these provide ideal evidence in support of the main thesis of the electronic theory of valency, that chemical affinity in all its various manifestations depends on the superior stability of certain numerical groups of electrons when under the influence of a positively charged nucleus In our opinion, this thesis now rests on an impregnable rock of experimental proof T M Lowry

Christian Huygens, 1629–95

Of all men of science whose lives were passed within the compass of the seventeenth century, none has a more lasting reputation than the Dutch mathematician, natural philosopher, and inventor, Christian Huygens Born on April 14, 1629, three hundred years ago, at a time when the work of Kepler, Galileo, Napier, Gilbert, and Harvey was slowly gaining acceptance, he lived to read Newton's "Principia," and during the course of his career saw the rise of experimental science, the erection of famous observatories, and the foundation of our greatest scientific societies, the Royal Society and the Paris Academy of Sciences, of the latter of which he was the first foreign associate

Huygens' birth, and his death on June 8, 1695, both took place at the Hague, and his tomb, like that of his illustrious countryman, Boerhaave, is there in St Peter's Church With advantages of birth, education, wealth, and position, Huygens possessed a studious and industrious mind, and an even and cheerful temper, and by the exercise of his brilliant intellect he raised himself to pre eminence among his contemporaries Trained in the law and for a short time attached to a Dutch embassy, he was all his life free to follow his own bent, and his long sojourn in Paris, where he enjoyed the seclusion of the Bibliothèque Roi, and his visits to England, no less than his investigations, discoveries, and inventions, led to his being esteemed by a wide circle of friends

The life and works of Huygens have been published and republished, but reference can be made to only one or two of his great contributions to the advancement of knowledge Attracted in his youth, like many of his fellows, to the construction and improvement of telescopes, on Mar 25, 1655, Huygens discovered Titan, the sixth, but the first seen, of the satellites of Saturn, and then gave the true explanation of the curious appearance of the 'triple planet' This discovery of Saturn's ring he made known in the form of a logogriph, which is reproduced by Grant in his "History of Physical Astronomy" In after years Huygens presented to the Royal Society an object glass of 122 feet focal length for an 'aerial telescope,' for the mounting of which Halley was commissioned by the Society to "view the scaffolding of St Paul's Church" to see if it could be used for erecting the object glass

From astronomy and telescopes Huygens turned to clocks, and on June 16, 1657, presented the first pendulum clock to the States General Described later in his famous work 'Horologium Oscillatorium," of 1673, a replica of the clock is to be seen in the Science Museum Of that famous work, it has been said that it contained original discoveries sufficient to have furnished material for half a dozen striking disquisitions, while 'the theorems on the composition of forces in circular motion with which it concluded formed the true prelude to Newton's 'Principia' and would alone suffice to establish the claim of Huygens to the highest rank among mechnaical inventors" This work, like his "Traité de la Lumière," in which he enunciated the undulatory theory of light, was written while he lived in Paris

Returning to his native country in 1681, Huygens continued his writings, and his last work, "Cosmotheoros," was in the printers' hands when he was attacked by the illness which proved fatal It is said that Flamstead recommended the "Cosmotheoros" to Dr Plume, archdeacon of Rochester, who was so struck with it that he left £1800 to found the well known Plumian professorship of astronomy at Cambridge

Obituary.

Dr Alex Hill

DR ALEX HILL, whose death was recently recorded in Nature, was born at Loughton, Essex, and educated at University College School and at Downing College, Cambridge; in 1880 he was elected a fellow of the College, from 1888 to 1907 he was Master of Downing, and from 1897 to 1899 Vice Chancellor of the University. He studied medicine and surgery at St Bartholomew's Hospital; in 1884–85 he was Hunterian professor of the Royal College of Surgeons.

The greater part of Dr Hill's life was spent in the advancement of learning; his services, not being confined to the routine of academic life, were given widely to educational causes. He assisted in the formation of the National Home Reading Union, of which he was the chairman from 1888 to 1908. He served as president of the Teachers' Guild of Great Britain, and was a member of various educational committees, including the Welsh Colleges Committee, 1907–8, and the Advisory Committee of the Treasury on Universities, 1901–6.

A versatile and an attractive writer, Dr Hill was the author of several books and papers on physiology and on other subjects connected with the profession for which he had been trained. His geniality, personal charm, and eloquence attracted crowded audiences in various parts of the country, when as a Gilchrist Lecturer he dealt with physiological and psychological subjects such as "Man under the Microscope" and "Dual Personality". His literary gifts were evident in his series of lectures on Browning and in his interpretation of the poet in his "Notes on Browning".

Dr Hill was zealous in his advocacy of university education, and having formed the conception of university institutions as centres of educational influence in areas not already served by universities, he strove to put his ideals into practice. With this aim in view he accepted an urgent appeal to become the Principal of University College, Southampton, a position which he took up in January 1913. His task was not an easy one, but he entered on it with characteristic enthusiasm; his winsome personality had an immediate effect on all branches of the College activities, and he was able to secure support for the new College buildings which had been planned for the present site at Highfield. The outbreak of the War so soon after he had entered upon his duties was a serious blow to the growing College; a large number of the staff and students joined the forces, and the new buildings were occupied as a war hospital. Dr Hill's own residence at Highfield Hall, which he had taken as a centre for the social activities of the College, he gave up to the Red Cross Society, and lived in a house near it in order to be able to assist the work of the hospital. Always a hard worker, his energy during the War was boundless, for in addition to carrying on his duties as Principal of the College, he took on himself the work of the Universities Bureau when his assistant secretary joined the forces. His recreation was in the garden attached to Highfield Hall, and even at this strenuous period of his life he rose early each morning to work in the garden, where he grew vegetables and flowers for the wounded soldiers in the hospital.

The work with which Dr Hill especially identified himself since 1912 was that of secretary of the Universities Bureau of the British Empire. The Bureau owes its inception to Dr Hill, who, when he resigned his position as Principal of the University College, Southampton, told the writer that there were two claims both very dear to him, those of the College and the Bureau; but whilst he felt that others could carry on the work of the College, the Bureau was his own child, and his one aim in life was to nurse it and to bring it to maturity.

A man of broad sympathies and wide vision, Dr Hill endeared himself to those who knew him. His tour with his family, so well described in his book "Round the British Empire," strengthened his vision and he felt more intensely that the work which he was undertaking was a means of cementing more firmly the bonds of Empire. Since 1920, although his work was mainly in London, his home was in Southampton, and his connexion with the College maintained by his election as a vice president. He died at 'Granta,' Upper Bassett, Southampton, on Feb. 27, and leaves a widow, a son, and a daughter.

J. Eustice.

We regret to announce the following deaths:

M. J. Boussinesq, member of the Section of Mechanics of the Paris Academy of Sciences and author of a mathematical work on the theory of light, on Feb. 19, aged eighty six years.

Sir Anthony Bowlby, Bart., K.C.B., K.C.M.G., K.C.V.O., a past president of the Royal College of Surgeons of England, on April 7, aged seventy three years.

Dr Jonathan Dwight, president in 1923–26 of the American Ornithological Union, on Feb. 22, aged seventy years.

Dr H. B. Gray, formerly warden of Bradfield College, and president in 1909 of Section L (Educational Science) of the British Association, on April 5, aged seventy seven years.

Sir George Knibbs, C.M.G., Commonwealth statistician from 1906 until 1921, and president in 1923–24 of the Australasian Association for the Advancement of Science, aged seventy years.

Dr Thomas B. Osborne, since 1886 research chemist in the Connecticut Experiment Station, who was an honorary fellow of the Chemical Society of London, and was distinguished for his work on the chemistry of the vegetable proteins and related subjects, on Jan. 29, aged sixty nine years.

Sir Henry Rew, K.C.B., sometime Assistant Secretary, Ministry of Agriculture, and a past president of the Royal Statistical Society and of Section M (Agriculture) of the British Association, on April 7, aged seventy years.

Dr Thomas Scott, associated for many years with the Scottish Fishery Board Laboratory and known for his work on the smaller marine crustacea, especially copepoda, in recognition of which the University of St Andrews conferred on him the honorary degree of LL.D., on Feb. 25, aged eighty eight years.

News and Views.

THERE are two thinkers in England just now working on very similar lines, investigating the relations of science and art Both are 'emeritus' professors, Lloyd Morgan of Bristol, Alexander of Manchester, and every reader of any of their publications on the subject must be struck by the earnestness and penetration of their work and the palpable and complete sincerity of their minds It is much to be hoped that they will persevere and that Prof Alexander, who has already several lectures and pamphlets on the subject to his credit, will soon be able to bring out the systematic volume which he has in mind Prof Lloyd Morgan gave two lectures at Bristol last November entitled "Science and Drama" (University of Bristol), which really deal with the same topic He uses the term 'drama' in the widest possible sense in order to cover all forms of 'agency,' and while in the first he considers the question of 'agency' in respect of natural phenomena which are studied in science, in the second he examines in detail what Alexander has already said about the action of the mind in art, on the whole accepting it and adding certain glosses' of his own

PROF LLOYD MORGAN'S second lecture sums up and gives the author's own point of view in his now familiar phrase of 'emergence' Science and art, he tells us, both give entry to a realm which is transformed in contrast with the world of naive perception The square box, for example, which we see as we move about in a room is transformed by the most elementary operation of science into a cube We never see it as a cube but we think so consistently in a transformed mental attitude that we always say that what we see is really a cube The difference in this respect between the man of science and the artist is that for the latter it is always the appearance which in his sense is the real There is, however, in both cases the scientific and the artistic result, something added by the thinker or the artist In the latter case the artist transforms the real as he perceives it into something having an 'art value,' and it is in this process of transformation, whether of the artist himself or of those who follow him in appreciating his work, that Prof Lloyd Morgan finds the new or 'emergent' attitude of mind which is the keystone of his philosophy It is the turning point in mental development, and probably not attained by the animal or the little child Then comes a careful and stimulating analysis of Alexander's account of the same process The two philosophers by no means agree on all the points which arise, and it is this comparison of results which makes the discussion so interesting English writers have not hitherto equalled the best of the German, Italian, or French philosophers who have studied æsthetic, and it is therefore the more gratifying to find a pair of subtle and mature minds engaged in friendly competition to fathom the depths of one of the most fundamental problems of thought Both, it should be noted, agree in placing the decisive element in the thinking mind

IN a recent leading article in NATURE (Feb 16, p 233) the connexion between forests and agriculture as considered in the Report of the Royal Commission on Agriculture in India was considered In different parts of India, a study of the history of the past sixty years or so has resulted in the steady growth of an opinion which recognises that there is a definite relation between unchecked abuses in the forest (by axe, fire, and overgrazing) and subsequent forest degradation, erosion, drying up of the waters and covering up of valuable agricultural lands Those who have studied these problems in India will not, perhaps, be aware how widespread and important they have become in other parts of the world Recently (Feb 27–Mar 1) a three days' joint session of the American Forestry Association and the Florida Forestry Association was held at Jacksonville Fla, to discuss the position of the southern forests and their industrial, conservational and recreational significance to the United States The main object of the meeting, according to a *Daily Service News Bulletin* issued by Science Service, Washington, D C, was a consideration of the steps to be taken "to reclaim for full production the vast tracts of southern land that are better adapted for forest crops than for any other purpose" One of the sessions was devoted to a consideration of the fire evil "Forest fires in the south," it is said, "are different from those in other parts of the country in that most of them are deliberately started by cattle owners under the mistaken impression that burning improves pasture How to persuade these people that they are burning money out of their own pockets is one of the most pressing problems confronting southern forestry men" Forestry men in India have been engaged upon this problem for sixty years and more, and Florida foresters could doubtless study the work of the past in India with profit

MR E A SHERMAN, of the United States Forest Service, in dealing with the important problem of soil exhaustion and erosion as a result of the destruction of the forests, said "Our fields have been robbed of their fertility almost beyond human comprehension Millions of acres have, through our ignorance, been rendered relatively worthless The far sighted thrift upon which was founded that part of the common law which places a taboo upon waste is still sufficiently inherent in our people to assure us that it will be applied as soon as the man in the street realises the presence of that waste and its extent He will insist upon prohibiting forms of agriculture that result in a permanent shrinkage in our total agricultural domain Economic pressure and the pressure of public opinion will combine to exclude certain classes of land from cultivation until such time as such use justified the investment necessary to adapt them for permanent tillage Meanwhile such lands may serve a useful and very valuable purpose as forests Forestry use not only safeguards the fertility of the soil from destruction, but actually contributes to its upbuilding" Mr Sherman in the above words

might have been speaking for many parts of the British Empire where problems of the kind, through mismanagement or ignorance in the past, are urgently demanding a solution

AT the quarterly meeting of the Grand Council of the British Empire Cancer Campaign held on Monday, April 8, the summary of the recommendations made by the Committee of the International Cancer Conference held last July was passed to the Investigation Committee of the Campaign to take action in initiating executive action on the proposals In the matter of radium and X rays, the Committee stresses the necessity for the institution of standardised records of results of patients treated by radium and X rays, and urges that the Campaign, in collaboration with the Medical Research Council and the Ministry of Health, should invite all institutions using radium and X rays to utilise an agreed form of record The Grand Council received the final reports on the subject of the Garton Prize, which has been instituted by the British Empire Cancer Campaign for the purposes of promoting investigations into the nature, causes, prevention, and treatment of cancer It was announced that a medal, with an honorarium of £500, will be awarded to the person, or group of persons, who shall submit the essay embodying the results of original investigations which, in the opinion of the judges appointed by the Grand Council, is the best contribution towards "The Early Diagnosis of Cancer"

THE recent presentation by Messrs Thos W Ward, of Sheffield, to the North Eastern Railway Museum at York, of some old rack rails and wheels from the Wylam wagon way has attracted considerable attention in the Press, and the Wylam wagon way has been referred to as the earliest railroad in the world On such matters there is often confusion of thought, and it should be remembered that railroads existed a very long time before locomotives were introduced Longitudinal wooden timbers were adopted on roads in mining districts in the fifteenth century and their use in the north of England was a factor in the development of our coal industry By the beginning of the nineteenth century they were in general use, but all haulage was by horses Cast iron plates or edge rails were introduced towards the end of the eighteenth century All such railroads were, however, private concerns, and the first public railroad was the Surrey Iron Railway, which was completed to Croydon in 1803 and to Merstham in 1805, but was never carried as far as Portsmouth, which was its intended destination The Wylam line is of course bound up with the introduction of the steam railway about ten years later

IN a paper read to the Newcomen Society on Mar 27, Mr W A Benton dealt with the subject of weighing heavy loads, and especially with the invention of the compound lever machines by John Wyatt of Birmingham Peoples of oriental or classical antiquity possessed no other weighing machines except those of the equal armed balance and the steelyard, and the maximum capacity of such machines during the Middle Ages does not appear to have exceeded one or two tons One such high capacity wooden beam has survived at Neisse, in Prussia The claims sometimes made that the compound lever weighing machine was first used by the Italian physician, Santori Santoria (1561–1636) do not appear to be substantiated, though he introduced the practice of weighing his patients During the eighteenth century huge steelyards were introduced for weighing loaded carts, two specimens of which still exist in England, one at Soham, Cambridgeshire, and the other at Woodbridge, Suffolk Wyatt's invention was made about 1744, and the machines with compound levers are described in encyclopædias at the end of the century An examination of the Wyatt manuscripts, however Mr Benton said, failed to throw much light on the early history of Wyatt's invention, which forms the basis of all platform weighing machines to day A carpenter by trade, Wyatt was born near Lichfield in 1700 and died on Nov 29, 1766, his tomb being in the churchyard of St Philip's, Birmingham Mr Benton was able to illustrate his paper with lantern slides and models, some of the latter coming from the historical museum of Messrs W and T Avery, Ltd, Birmingham, whose works occupy the site of Boulton and Watt's famous Soho Foundry

AMERICAN museums continue to make great advances in their efforts to reach and teach the people In connexion with the Brooklyn Children's Museum, a new building—larger and finer than many of the local museums of Britain has just been opened to the public, and the increase of space has suggested many improvements in the storing and lending of material The library section, in addition to its books which are open to inspection by the children, possesses 8000 lantern slides catalogued on the Dewey system, a file of 5000 pictures so indexed that any teacher or child may borrow a set of them for special school work, and a collection of excerpts from the *National Geographic Magazine*, arranged according to subject and also available for borrowing It is still more interesting to learn that from the hall in which the Hooper Memorial Loan Collections are displayed children may borrow and take home small cases containing mounted birds, which they take off the shelves just as they might borrow a book A new type of history room is to be created at the Brooklyn Children's Museum as the result of a gift of 15,000 dollars by Mrs John Mills The room will contain a unique collection of twenty five historical scenes in miniature, illustrating significant events in the progress of the human race They will begin with the cave men and will show that ideas, rather than wars and weapons, have been responsible for the progress of mankind Further groups will tell of the discovery of painting, the development of the drama, the science of navigation, the application of steam and electricity, and the conquest of the air Mr Dwight Franklin, of New York, who is already well known for this class of work, will prepare the historical groups, and it is expected that the creation of the twenty five groups will occupy about two years

IN paper mills and rubber factories trouble often arises from large sparks due to the statical electricity

generated by the running machinery Various remedies have been suggested for reducing the fire risk due to this effect In a recent *Daily Science News Bulletin*, issued by Science Service of Washington, D C, a somewhat novel method used by a large Russian rubber factory is described for avoiding the danger of fire In the factory, when the rubber solution flows over the fabric base and dries on it, large charges of static electricity are produced by the friction of the rubber covered fabric with parts of the drying machinery When the stress at the surface gets greater than the electric strength of air, a hot 'fat' spark is produced similar to the ignition spark of a magneto, and this may start a fire, or cause an explosion as the air in the drying room is always saturated with highly explosive vapours A usual method in Great Britain is to use a fine wire brush to collect the charges and let them pass to earth, but sparks cannot be altogether prevented in this way In the Russian State factory in Leningrad a capsule of radium is placed near the point where the electricity is generated The radiations from the radium ionise the air, and so the electric charges flow through it harmlessly to the earth The cost of the installation is very low, as one milligram of radium is quite sufficient to prevent sparks from taking place, and it will doubtless last for many years The method has been known for a long time, but this industrial application is a useful one

THE first Young Farmers' Club in Great Britain was formed by United Dairies, Ltd, at Hemyock in Devon in 1921, and from the start the movement has been remarkably successful Whereas in 1924 there were only about 30 clubs and 600 members, now there are 100 clubs with a membership of about 2000 A fresh indication of enterprise is the recent issue of a monthly illustrated journal entitled *The Young Farmer* (National Association of the Young Farmers' Clubs, 26 Bedford Square, London, W C 1, price 3*s* a year) Much interesting information is given in the first issue by various authors concerning the aims, growth, and activities of the movement From the outset it was realised that though it was ideal for the organisation to be independent and self supporting, yet some outside help would be necessary for a start In 1924 the Ministry of Agriculture accepted a measure of responsibility, and now the support of the National Council of Social Science has been secured, and a National Association of Young Farmers' Clubs has been formed under its auspices Such centralisation, together with the help of the new journal, should do much towards creating corporate feeling between the individual clubs Titles of articles in the first issue, such as "My Experiences at the Dairy Show in 1928," "Coaching an International Cow Judging Team," "Boys and Girls in Rural Ontario," "A Year's Work in a Bee Club," serve to indicate the varied nature of the contents

THE considerable extension of fur farming in Great Britain during the last few years suggests that the attention of inquirers should be directed to a leaflet just issued by the United States Department of Agriculture, "Recommendations to Beginners in Fur farming" In gives in summary form, with references to further literature, general information on how to make a start areas suitable for farming, species suitable for propagation, where to obtain breeding stock The instruction is scanty, but it may be readily supplemented by consultation of the special publications of the Department, which are mentioned

THE Czechoslovak National Research Council, which is incorporated in the International Research Council, concluded its fifth year's activity at a general meeting held in Prague on Mar 16 The president, Prof Syllaba, opened the meeting by defining the functions of the International Research Council and the Czechoslovak National Research Council, which latter is an offspring of the Czech Academy of Sciences In conclusion, Prof B Němec delivered an interesting lecture on "International Aspects of Czech Science," in which he pointed out the twofold duties of scientific workers of a small nation, namely, to cultivate their national science and to present their achievements before the international world The annual report which has recently been published, describes the activities of the ten sections of natural sciences, medicine, and engineering, and gives the names of the 82 members

BY an Act of Congress the United States of America have established a Gorgas Memorial Institute of Tropical and Preventive Medicine in Panama, and the memorial laboratory has just been opened Surgeon General William C Gorgas, who died in 1920, went to the isthmus of Panama to report on the sanitary conditions of the Canal Zone in 1904, he was appointed chief health officer for the region, which was then notorious for malaria and yellow fever His work there, a monument to scientific and administrative hygiene, made the Canal Zone an inhabitable and even healthy area The first director of the new laboratory is Dr Herbert C Clark, who was with General Gorgas in the Canal Zone for several years Congress has authorised a permanent appropriation of 50,000 dollars a year for maintenance, and Latin American governments have been invited to contribute up to 75 per cent of the amount given by the United States

THE Bureau for Contraceptive Advice, Baltimore, Maryland, has issued its first statistical report, compiled by Prof Raymond Pearl The number of women (all married), attending was 168, their average age was just under 31 years, and the average duration of marriage 12 3 years One half of the women who attended the Bureau had been pregnant more than six times and had borne five or more children before they came Such reproductive rates are not conducive to either private or public health, and the figures given demonstrate the value of such a clinic as a health measure and lend no support to some of the objections that have been advanced against contraceptive measures

A LEADING article in the latest number of the *Scottish Naturalist* entitled "More Opportunities for

Naturalists Natural History as a Profession," points out the need for the creation of trained biologists to fill the increasing number of posts available in Great Britain and its colonies "There never has been a time when so many opportunities offered themselves for young men who desire to follow natural history as a career, nor a time when so few men could be found to fill the posts that await them" It is shown that the posts in question cover a wide variety of work, giving scope for outdoor observation and opportunities for biological research, and an indication is given of the scales of salary which may be expected here and abroad

The Report on the Health of the Army ' for the year 1927 has recently been issued (London H M S O) The incidence of sickness among soldiers during the year was somewhat higher than that of the preceding year, being 467 7 per 1000 of the strength, accounted for by the high incidence of infection during the early months of the defensive occupation of Shanghai The principal causes of admission to hospital were malaria, 9265 cases, venereal diseases, 9186 cases, and inflammation of tonsils, 6322 cases The high incidence of tonsillitis still remains unexplained As in the previous year, inflammation of the middle ear heads the list as cause of invaliding Diphtheria was comparatively prevalent with 317 admissions, while the enteric groups of fevers numbered only 239 cases for the whole army, including India, a remarkable record

Prof Pieter Zeeman, of the University of Amsterdam, has been elected an honorary fellow of the Physical Society of London

The George Darwin Lecture of the Royal Astronomical Society will be delivered at the meeting of the Society on May 10, by Prof E Hertzsprung, who will take as his subject The Pleiades

Prof F O Bower emeritus professor of botany in the University of Glasgow, will give the Huxley Memorial Lecture at the Imperial College of Science and Technology, London, S W 7, on May 3 at 5 30 P M His subject will be 'The Origin of a Land Flora reviewed Twenty one Years after Publication

The fourteenth Guthrie Lecture will be given before the Physical Society by Prof P W Bridgman, Hollis professor of mathematics and natural philosophy in Harvard University, on the properties of the elements under high pressures, at 5 o clock on April 19, in the Imperial College of Science, Imperial Institute Road, South Kensington Admission is free without ticket

It was announced by the president of the Linnean Society of London, at the meeting held on April 4, that the Linnean Medal, which 'is awarded each year to an eminent biologist as an expression of the Society s estimate of his services to science," is to be given to Prof Hugo de Vries, the veteran emeritus professor of botany in the University of Amsterdam, who is best known for his mutation theory of the origin of species

The gold medal of the Institution of Mining and Metallurgy has been awarded conjointly to the Hon William Lawrence Baillieu and William Sydney Robinson "in recognition of their services in the development of the mineral resources of the Empire, with special reference to the zinc and lead industries of Australia" The medal (in duplicate) will be presented at the annual general meeting of the Institution to be held at Burlington House on Thursday, May 16

The following office bearers were elected at the meeting of the Royal Philosophical Society of Glasgow on Mar 27 —*Vice President* Mr Robert A Burr, *Members of Council* Prof E P Cathcart, Dr James W French, Mr Thomas Henderson, Mr Andrew A Mitchell, *Hon Treasurer* Sir John Mann, *Hon Librarian* Dr James Knight, *Hon Secretary* Dr Charles R Gibson, *Hon Auditors* Mr Alex Murdoch, Mr John T Tulloch, *Acting Secretary* Dr James M Macaulay

A special feature of the first annual conference of the International Society of Experimental Phonetics, to be held at Hamburg on July 24–31, will be the provision for practical demonstrations and exercises in the study of speech by the graphic method Each participant will have an opportunity of becoming familiar with this method of investigating language, dialects, speech defects, the speech of the deaf, and nervous diseases This method is that of the Abbé Rousselot with the later improvements Information concerning the conference can be obtained from Prof E W Scripture, Strudelhofgasse 4, Vienna

At the annual general meeting of the Ray Society held on Mar 21, the following officers were re elected *President* Prof W C M Intosh, *Treasurer* Sir Sidney F Harmer *Secretary* Dr W T Calman Dr R W T Gunther was elected a vice president, and Mr R Adkin and Mr R Gurney were elected new members of council In the report of the council it was announced that the third and final volume of the ' British Hydracarina, ' by Mr C D Soar and Mr W Williamson, would shortly be published, and that the issue to subscribers for 1929 would be a volume on 'The Planktonic Diatoms of Northern Seas," by Dr Marie V Lebour A work on The Aquatic Stages of British Dragonflies, ' by Mr W J Lucas, was announced as being in preparation for publication at a later date

Among recent appointments in scientific and technical departments made by the Secretary of State for the Colonies are the following Mr G N Herrington has been appointed agricultural instructor in the Education Department, Nigeria Mr A W Anderson, recently one of the Ministry of Agriculture and Fisheries' advisory officers, is to be a superintendent of agriculture, Nigeria, and to take charge of the new stock breeding farm at Samaru Mr D A Langdon has been appointed a produce inspector, Nigeria, and Mr T D Lloyd Jones a veterinary officer in the same Colony Mr N R Reid has been appointed a veterinary officer in Tanganyika Territory Among the recent transfers and promotions are the following Mr J R Ainslie, senior conservator, to be deputy director of forests, Nigeria, and Mr C F Vetch, conservator of forests, Nigeria, has been appointed to succeed him as senior conservator Mr

D D'Emmerez de Charmoy, assistant director, has been appointed director of agriculture, Mauritius

MESSRS BERNARD QUARITCH, Ltd, 11 Grafton Street, W 1, have just issued an important catalogue (No 424) of some 1800 works relating to science, mainly of zoological and geological interest As is usual with lists circulated by this house, many rare items and long runs of serials are included The catalogue is one that should interest collectors and librarians

THE new catalogue of engineering and industrial instruments issued by Messrs Negretti and Zambra is a well illustrated quarto volume of 460 pages It deals to a large extent with thermometers of all kinds, from spirit thermometers to electrical thermometers, suitable for near or distant stations, and gives a considerable amount of very useful information about the principles on which they work and the precautions necessary in setting them up and caring for them in use Barometers, pressure gauges, tank gauges, hydrometers, and hygrometers receive similar treatment and a thumb index facilitates quick reference

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —Temporary assistant quantity surveyors under the Mines Department—The Under Secretary for Mines, Establishment Branch, Mines Department, Dean Stanley Street, S W 1 (April 18) An assistant bacteriologist for the city of Liverpool—The Town Clerk, Municipal Offices, Liverpool (April 22) A temporary assistant bacteriologist for research in fabric materials—The Secretary, Admiralty (C E Branch), Whitehall, S W 1 (April 27) An education secretary for the borough of Cambridge—The Town Clerk and Clerk to the Local Education Authority, The Guildhall, Cambridge (April 27) A chief assistant and two other assistants for the Scottish Society for Research in Plant Breeding under the Society's scheme of research into virus disease of potatoes—The Secretary, Scottish Society for Research in Plant Breeding, 3 George IV Bridge, Edinburgh (April 30) A lecturer in education in the University of Sheffield—The Registrar, The University, Sheffield (April 30) A lecturer in mathematics at the Heriot Watt College, Edinburgh—The Principal, Heriot Watt College, Edinburgh (May 1) An assistant at the Commonwealth of Australia Solar Observatory, near Canberra —The High Commissioner for Australia, Australia House, Strand, W C 2 (May 2) A junior technical officer at the Royal Aircraft Establishment, to assist in the experimental development of electrical equipment for use in aircraft—The Chief Superintendent, R A Establishment, South Farnborough, Hants (May 3) A principal of the Paisley Technical College —The Secretaries of the College, 3 County Place, Paisley (May 3) A demonstrator in physics, a demonstrator in zoology, and a demonstrator in inorganic and physical chemistry at Bedford College for Women—The Secretary, Bedford College for Women, Regent's Park, N W 1 (May 4) A director of museums of the City of Liverpool—The Town Clerk, Municipal Offices, Liverpool (May 7) A professor of zoology in the Egyptian University, Cairo—The Dean of the Faculty of Science, Egyptian University, Cairo (May 19) A laboratory assistant at the College, Cheltenham—The Senior Science Master, The College, Cheltenham

Our Astronomical Column

THE APRIL METEORS —These meteors are due on April 20 or 21, but the moon, being full on April 23, will be a bright object at the time and obscure small meteors However, the shower occasionally exhibits brilliant objects, so that it may be well worth looking for though the character of its display this year cannot be definitely foretold The period of revolution of its supposed parent comet was computed to be more than 400 years, but rich showers of Lyrids were witnessed in 1803, 1851, 1863, and other years, so that a short period apparently corresponds with some of the most abundant returns of the meteors It is important to note the strength of the annual displays, so that the time of revolution of its more active returns may be determined Its radiant is at 271° + 33° on the night of maximum, but the centre of radiation travels eastwards one degree per day

THE NUCLEI OF PLANETARY NEBULÆ —Mr van Maanen deduced the trigonometrical parallaxes of a number of nuclei of planetary nebulæ from photographs taken at Mt Wilson He derived the mean parallax 0 012″, and the mean absolute magnitude 8 1 for the nucleus Mr B P Gerasimovic notes in *Harvard Bulletin* No 864 that such data as exist for the proper motions and radial velocities of the planetary nebulæ indicate a considerably greater mean distance than that found by van Maanen. He makes several different estimates of their mean distance, (1) by their mean galactic latitude, which is assumed to be due to the sun's departure from the galactic plane, (2) by applying Oort's results on galactic rotation, (3) by using the analogy between the nebular nuclei and novæ, (4) by combining the proper motions found by van Maanen with the mean radial velocity of planetary nebulæ found at the Lick Observatory, which is 37 km /sec The mean absolute magnitudes found by these methods are 4 3, 4 6, 4 0, 5 9 respectively the weighted mean is 4 9, which is more than 3 magnitudes brighter than van Maanen's value, there is therefore good reason for thinking that his parallaxes for these objects are four times too large, though no explanation of this error has been found

THE ORBIT OF ETA CORONÆ —*Astr Nach* 5615 contains an exhaustive study of the orbit of this star by E Silbernagel, who has devoted himself for some years to the re determination of the orbits of binaries The duplicity was discovered in 1781 by Sir W Herschel, and as the period is less than 42 years, 3½ revolutions have been completed since then About 500 observations are employed, and the personal equations of the observers are determined The following is the final orbit:

T	1892 385	n	8 6490°
Ω	23 717°	a	0 907″
i	59 025		
ω	219·907		Period 41 623 y
e	0·2763		

Research Items

Festivals of the Hos of Kolhan.—Mr. D. N. Majumdar describes in the *Journal and Proceedings of the Asiatic Society of Bengal*, N.S., vol. 23, No. 3, the seven important worship festivals of the Hos which take place at different seasons of the year. It is noteworthy that in certain feudatory states in Orissa, where the Hos live in close association with the Oriya speaking peoples, while the latter take part in the festivals of the Hos, they are not allowed to take part in their dances, when men and women mingle freely, as intermarriage is not allowed. The festivals are not held at fixed dates, but depend upon economic conditions. When the granaries are full and the Hos are free from other engagements, the priest fixes a day for a festival, each village deciding for itself, so that any given celebration may extend over as much as two months, when the whole area of Kolhan is taken into account. The principal festival is the Maghe, which is held in January and February. Its meaning is obscure, but it seems to be connected with fertility. All villagers even if working in remote districts, must return to take part. It entails five days of ritual observances with *pujas* and sacrifices to the village deity. On the first day the sacrifice is connected with the cattle, on the second rice beer is offered by the priest and his wife. The third day is purificatory, in preparation for the marriage festival of the fourth day, which is the main function of the celebration. On this day the priest is escorted to take a ceremonial bath. He then sacrifices a cock and hen. A second hen, which is offered to the god, is not sacrificed by the priest, but is stoned to death by the villagers. In the dance which follows obscene songs are sung and obscene practices observed for the purpose of increasing the procreative power of the tribe. On the fifth day the expulsion of spirits takes place, when the villagers arm themselves with sticks, four or five feet long, and hunt the spirits throughout the village with invocations which are unintelligible even to themselves.

Early Persian Zoology.—The earliest exposition of Persian zoology is contained in a compendium of science, the "Nuzhatu-i-Qulûb," written by Mustaufi about A.D. 1340. One of the few extant zoological treatises of the Islamic East, apparently the only one the primary object of which was scientific rather than literary or philological, its chapters are of much interest as illustrating the level of zoological knowledge at the time and indicating the sources from which that knowledge sprung. In a learned treatise upon the subject (*Isis*, vol. 11, December 1928), Dr. John Stephenson traces the influences which are apparent in Mustaufi's zoology, gives examples of the treatment of real and fabulous zoology, of the bearing of the work upon medicine, and of the surgical uses of animals and their several parts. In an interesting comparison with European zoological works of the same period, he points out striking resemblances with the zoological text-book of Christianity in medieval times, the "Physiologus" and, since direct borrowing may be ruled out of the question, he regards these similarities as due to the descent of tradition from a common source. The general level of knowledge is much the same as that displayed by the thirteenth century English Franciscan, Bartholomew de Glanvilla, who borrowed from the "Physiologus," and, like the Persian author, had his mythical creations, mermaids, fauns, and satyrs, as well as more realistic monsters, such as the onocentaur, offspring of the bull and the ass.

Evolution of Human Tools.—An unusual study in human evolution has been made by Mildred Fairchild and Dr. Hornell Hart (*Scientific Monthly*, January 1929), in which they trace in a general way the development of cutting tools from the earliest chipped flints to the machines of the present day. The existence of such tools from the early stages of man's development affords the longest and most complete series of data available for the estimation of man's cultural progress. The tools present five variables upon which efficiency depends: (1) keenness and durability of the cutting edge, (2) differentiation and specialisation, (3) effectiveness of mechanisms employed to apply the blade to the materials to be cut, (4) utilisation of auxiliary power, and (5) mastery displayed in the technique of manufacture. Reducing these elements of efficiency to a numerical basis and combining all in a graph of progress, the authors produce a curve which, showing little rise over a long period, makes a sudden and rapidly increasing ascent during the past 8000 years. Whereas in earliest times thousands of years indicated the unit of progress, now each decade or each year shows swift advancement. The more and more rapid acquisition of new elements is not due to our lack of knowledge of early portions of the series; the increasing speed of invention is an unmistakable feature of the series itself.

Birds of Inner London.—Much has been written about the birds of London and the lists published by the committee in charge of the bird sanctuaries in the Royal Parks furnish useful notes on fluctuations of species from year to year. But no attempt has hitherto been made to compile a complete list of the birds which have been seen in Inner London as a whole. The area selected by A. Holte Macpherson for his interesting article on the subject (*British Birds*, March 1929) extends 2½ miles due north and south of Charing Cross and 4 miles due east and west of that point. Within this district the author is able to record a list of 126 species, of which 21 breed regularly, 8 others have been known to breed during the present century, and the remainder are visitors, 20 of which may be regarded as regular and 77 as putting in only an occasional appearance. Perhaps the most striking feature of the list is the variety of ducks and waders recorded. The occurrence of such as whimbrel, common and jack snipe, and woodcock, and of gadwall, scaup, and scoter, suggests that the mud banks of the Thames at low water may yet reveal further additions to the list, now that so satisfactory a basis has been laid for future observations.

New Aquatic Rodent from Africa.—Until the expedition organised by the Field Museum and the *Chicago Daily News* returned from its explorations in Abyssinia, only one aquatic rodent was known from Africa, namely, *Dasymys*. Now a second murine rodent, with rather pronounced aquatic modifications, has been found in a small mountain stream near the source of the Blue Nile. Its adaptations more closely resemble those of aquatic rodents in other parts of the world than of *Dasymys*, and since it shows no special affinities to the latter, the two African 'water rats' probably had independent origins. For this outstanding form Wilfred H. Osgood has created a new genus and species, *Nilopegamys plumbeus* (*Field Mus. Nat. Hist., Publication* 250, November 1928). Its particular adaptations for aquatic life are mainly in the character of the fur, the reduction of the external ears and the enlargement of the hind feet,

and in these respects it is reminiscent of the South American *Ichthyomys*, to which also it bears some resemblance in its skull But the skull is not greatly modified and the suggestion made is that the new 'water rat' may have been derived at no very remote period from one of the common types widely distributed in central Africa

GRAFTING EXPERIMENTS IN TWO DAY CHICKS — P D F Murray (*Aust Jour Exp Biol*, vol 5, part 4, Dec 1928) has made chorio allantoic grafts of lateral pieces of two-day chicks, taken from the region forming the posterior limb by making an anterior transverse cut posterior to the hindmost somite then formed, a posterior cut in front of the anterior end of the primitive streak, a longitudinal median cut lateral to the vertebral plate The grafts show cartilaginous structures interpreted as attempts at limb formation, and it is concluded that no essential influence is exerted by the somites on the development of limbs, and the author adduces reasons for the view that if the limb rudiment at two days could be completely isolated self differentiation would occur, that is, the rudiment of the hind limb is already determined at this stage The nervous system exerts no essential influence on the development of the limbs of the chick In three cases the endodermal and splanchnopleural components of the grafts have given rise to short pieces of intestine with epithelium, corium, circular and longitudinal muscle layers, hence small pieces of the region of the alimentary tract are able to develop in the absence of the other regions of the tract

INTESTINAL MUSCLE OF THE CRANE FLY —S Maziarski (*Bull. Int Acad Polonaise Sc Lettres*, 7 B, 1928) has investigated the histology of the muscle of the alimentary tract of several species of *Tipula* (crane fly) Opinions as to the nature of the muscular elements—whether they are smooth or striated—have been contradictory, but the author states that undoubtedly all the muscular elements of the intestine are in the category of striped muscle All the contractile elements and their ramifications by which they anastomose exhibit a characteristic longitudinal and transverse striation, the longitudinal due to the myofibrillæ in the sarcoplasm The elongate muscular elements, each with a single nucleus and a sarcolemma sheath, exhibit numerous ramifications either terminal or lateral, some short and others apparently composed of a single myofibril, which anastomose directly with neighbouring fibres to form a network The anastomosis always takes place at the level of the membrane of Krause, which confirms the view already expressed by many other histologists that this is distinct from the contractile substance and represents a more plastic and more resistant supporting material The intimate relations between the fibres (cells) suggest that the contractile elements have lost their individuality and form a muscular syncytium

COTTON —The reports received from experiment stations during 1927–28 have been issued by the Empire Cotton Growing Corporation in a bulky volume of some 270 pages, plus photographs, diagrams, etc This lengthy document is preceded by a very valuable, concise summary of its contents by Dr J C Willis Dr Willis points out the inevitable difficulty of the field experimenter in that his rainfall practically always departs from the average (and the same may be said of every measurable climatic factor), and thus in the twenty climatic records from ten cotton experiment stations in the last two seasons, five may be classed as good years, ten medium, and five bad Some experiment stations are probably situated in climates which are not well suited for existing varieties of cotton, and here, as at Fiji, where the weather is probably unusually wet for cotton, something may be done by hybridisation and selection to produce a new variety more suitable to the climate In South Africa, the immediate problem has been the production of a variety showing resistance to the jassid pest, and remarkable progress appears to have been made with the selection and multiplication of suitably resistant strains These strains, developed at the Barberton Station, seem likely also to be successful in Rhodesia In Queensland good progress seems to have been made in dealing with the pink boll worm, whilst in Fiji it is very interesting to learn that the boll worm pest is apparently kept in check by its parasitic enemies Boll shedding before the crop is mature is often a great source of trouble with cotton, and in Uganda definite progress seems to have been made with the breeding of varieties with lower rates of boll shedding All who are interested in any phase of the field study of the cotton plant its growth the control of its parasitic enemies the breeding of new strains, etc, will find the Report of interest and value It is published by the Empire Cotton Growing Corporation, Millbank House, Millbank London S W 1

GLADIOLUS —The wide range of species of *Gladiolus* in South Africa is illustrated to some extent in the beautiful coloured plates accompanying the article by Mrs Bolus on this genus in the *Journal of the Botanical Society of South Africa* part 14, 1928 In the notes on p 3 of the same journal attention is directed to the horticultural possibilities that are suggested by experiments in hybridisation with some of this species Thus at present there are no scented and no blue forms among the *Gladiolus* hybrids under cultivation whilst amongst the South African species blue flowered ones occur and some of the wild species have a powerful and delicious fragrance Such hybridisation experiments would seem very suitable work to be carried out at the National Botanic Gardens Kirstenbosch, but unfortunately the income of the Gardens does not permit the possession of any scientific or technical staff whatever so that such experiments in the Gardens could only be carried out to the detriment of other work In the same number of the journal, Mr J W Mathews, curator of the Gardens, contributes some notes on the cultivation of the native South African gladioli

NEW PROJECTION FOR WORLD MAPS —In the *Geographical Journal* for March, Mr S W Boggs describes a new equal area projection that should be useful in statistical maps It is an equal area projection which is an arithmetical mean between the sinusoidal equal area projection of Sanson and the elliptical equal area projection of Mollweide Inequality in linear scales near the equator is scarcely noticeable, and the same is true between latitudes of, say, 60° and 75° This feature is an improvement on Mollweide Angular distortion is less than in Sanson in latitudes below 62°, above 68° or thereabout the angular distortion is less than in Mollweide The author describes it as a eumorphic equal area projection He points out that this projection, like those of Sanson and Mollweide, having straight parallels and converging meridians, lends itself to 'interrupted' construction in gores or lobes which much enhances its value for distributional maps

EARTH MOVEMENTS IN CALIFORNIA —The United States Coast and Geodetic Survey is continuing its researches into earth movements in the western United States by comparing the position of stations as determined by old and new triangulation In *Special Publication* No 151, Dr W Bowie discusses the results

of recent work in California The comparison is generally between determinations made prior to 1900 and those made between 1922 and 1925 Many stations show no movement The greatest movements have occurred close to the fault line of the earthquake of 1906 Stations more than twenty miles from the fault were affected but only slightly The differences are small and seldom exceed one metre The trend of the changes is to the south eastward, on the east of the fault where they are most noticeable Dr Bowie suggests that investigations of this nature should in the future be done by means of short arcs of triangulation extending across the fault line or zone to a distance of about twenty five miles on both sides The accuracy can be made great enough to detect movements of about one tenth of a foot in a mile He prefers this method to that of measurements between monuments placed across the fault zone in a straight line This plan involves the difficulty of measuring with tapes over broken ground

INDIAN JURASSIC AMMONITES —The third part of Dr L F Spath's 'Revision of the Jurassic Cephalopod Fauna of Kachh (Cutch)" (*Palæont Indica*, N S, vol 9 mem 2, pp 163 278, plates 20 47, 1928) deals with the super family Stephanoceratidæ, represented by about 500 specimens This is divided into five families the Macrocephalitidæ with 7 genera, the Eucycloceratidæ with 4 genera, the Pachyceratidæ with 2 genera, the Mayaitidæ with 5 genera, and the Reineckeidæ with 6 genera

JAPANESE PALÆONTOLOGY —The rich fauna of the Lower Tertiary of the island of Kyushû, Japan, has been described by T Nagao (*Sci Rep Tôhoku Imp Univ Sendai*, ser 2, Geol 12, 1 1928, pp 11 140, plates i xvii) It consists mainly of lamellibranchs and gasteropods, but some foraminifera, echinoids, nautiloids crabs, and fishes are also found Three horizons are recognised The lowest is regarded as Ypresian or Lutetian in age, the middle as Upper Eocene, the upper as Oligocene In the same publication (pp 141 152 plates xviii xxiii) H Yabe and S Toyama give an account of the rock forming algæ from the Jurassic and Cretaceous deposits of Japan Some of the species are referred to genera found in England (*Girvanella, Solenopora*), others belong to new genera

VACUUM TECHNIQUE —Several attempts have been made to find a substitute for mercury for use in high vacuum pumps, but they have not hitherto met with any conspicuous success metals other than mercury have undesirable properties, and it had been thought that organic substances were too liable to decomposition to be of use C R Burch, of the Metropolitan Vickers Company, states, however, in the issue of the *Proceedings of the Royal Society* for Mar 6, that it is possible to run a condensation pump satisfactorily with some of the fractions obtained in the vacuum distillation of petroleum jelly, when both the speed of pumping and the degree of vacuum reached compare favourably with those obtained when mercury is employed The petroleum products have the additional advantage that their vapour pressures are decidedly less than that of mercury at room temperatures The author has also isolated a number of greases, the vapour pressure of which is less than a microbar at 300° C, which should be extremely valuable for the lubrication of ground joints in vacuum apparatus which does not require to be heated

STARK EFFECT —Prof Stark's discovery of an electrical analogue of the Zeeman magnetic effect for spectral lines, although less widely applied in spectrum analysis, has recently become of importance in connexion with the wave-mechanics The distribution of intensities in the Stark patterns for the Balmer series of atomic hydrogen has been predicted by Schrodinger, and experiments to test his theory have now been made by J S Foster and L Chalk (*Proceedings of the Royal Society*, Mar 6), and by H Mark and R Wierl (*Zeitschrift fur Physik*, Feb 25) Dr Foster has made use of the natural electric fields in the cathode dark space of a discharge tube, and finds distributions of intensities which agree with those predicted by theory The other investigation was made upon the light emitted from a beam of positive rays passing through an auxiliary electric field, and the agreement between theory and experiment is less good The origin of these discrepancies is not clear, but it may be, as H Mark and R Wierl suggest, that the experimental conditions employed do not conform completely with those contemplated in the theoretical analysis Dr Foster has contributed a second paper, on the Stark effect in neon, to the same issue of the *Proceedings*, which also contains a paper by J K L MacDonald on the Stark effect for some lines in the violet part of the secondary spectrum of hydrogen

COMBUSTION OF CARBON MONOXIDE —Prof W A Bone s experiments on the combustion of dry mixtures of carbon monoxide and oxygen have been subjected to a certain amount of criticism on the grounds that inadequate precautions had been taken to remove occluded hydrogen from the platinum electrodes between which the igniting spark was passed These objections appear to have been met satisfactorily in the reply which he has published in the issue of the *Proceedings of the Royal Society* for Mar 6, and some new experiments which are described there, in which the drying was, if possible, even more drastic than before, confirm his earlier result that the intensively dried mixture can be induced to react if only sufficient energy is supplied to initiate the explosion wave Prof Bone and his collaborators consider that the limit of intensive drying by phosphorus pentoxide is reached in about six months in small glass vessels such as those they have employed The energy required to start the explosion seems to depend both upon the nature of the electrodes used and upon the composition of the detonating mixture, but the numbers which are mentioned in this paper are all in the neighbourhood of one joule

ACTION OF ACETYLENE ON SELENIUM —Only very few accounts of experiments on the direct action of non metallic elements on organic compounds have as yet appeared in chemical literature The formation of thiophthen, $C_6H_4S_2$, by the interaction of acetylene and molten sulphur was observed by Capelle and confirmed by Oechsner de Coninck (1908), whereas, according to Meyer and Jacobson's "Lehrbuch," Sandmeyer established the formation of thiophen under such conditions In the *Rendiconti* of the Naples Academy of Physical and Mathematical Sciences for September–December 1927 (just received), Mazza and Solazzo give the results of an investigation on the action of acetylene on selenium Passage of the pure, dry gas over selenium heated to 250° 300° C yields an oily product, which may be resolved by fractional distillation into two compounds (1) Selenophen, C_4H_4Se, b pt 113° 114°, which is identical with the product obtained by Foà in 1909 by the action of phosphorus selenide on sodium succinate, (2) a new compound, selenonaphthen, C_8H_6Se, m pt. 53° 54°, b pt 207° 209°, which is the selenium analogue of thionaphthen and has an intensely nauseous odour This compound crystallises well and forms a golden-yellow, crystalline, slightly soluble picrate.

Research on Water Pollution

A COMMITTEE has been set up, under the chairmanship of Sir Horace Monro, to deal with the legislative and administrative aspects of questions relating to river pollution This committee considers that present legislative enactments are sufficient, and recommends the setting up of River Boards in the various watersheds of England Such Boards, having a call upon the rates, would be in a financial position to apply the laws against pollution, a costly activity which rarely appeals to private individuals They would be in a position to employ a technical adviser conversant with local conditions and with known means of dealing with noxious effluents It remains to be seen whether county councils will act on this advice and set up a series of Boards throughout Great Britain, similar to that in the West Riding of Yorkshire

Although much has been done recently in surveying rivers and locating sources of pollution, many of which could be stopped or at least ameliorated without putting undue burdens upon the rates or upon individual industries, there are also numerous questions which, in the interests of the public, have still to be worked out

With this aim in view, the Water Pollution Research Board was formed in June 1927, with Sir Robert Robertson as chairman and Dr H Calvert, chemical Inspector of the Ministry of Health, as part time director of research They have undertaken the three fold task "To collect and collate all pertinent scientific and technical information, so that it may be readily available for practical application by those who are concerned with water supply and the disposal of polluting liquids, to encourage and co ordinate relevant scientific research in this country, and to undertake such investigations as are necessary in the public interest and not otherwise provided for"

A good start has been made The monthly summaries of current literature, of which some seventy copies are distributed, are excellent and will be of material assistance not only to those concerned with water purification and wastes disposal but also to many workers in hydrobiology In the report of the Board for the year 1927–1928 (H M Stationery Office, 6*d*) an account is given of investigations now proceeding and of plans for the near future

The disposal of effluent waters from beet sugar factories presents a problem which had early in the year been 'farmed out' by the Ministry of Agriculture and Fisheries for investigation at Rothamsted Each factory uses some 3½ million gallons of water daily, of which nearly half a million gallons are discharged containing putrifiable matter comparable to 0 2 per cent sucrose It is found that by sprinkling this water over a biological filter at a rate of 100 gallons per square yard daily, its putrescibility is reduced by some 80 per cent Trial filters were erected at the Colwick factory and filled with different media Two were seeded with active growth from a sewage filter, but this inoculation had no observable effect on the maturing of the filters The growth on coarse gravel consisted of thickly matted fungi, while on the finer media the growth was soft and composed chiefly of bacteria, the flora and fauna on the filters differed and were distinct from the flora and fauna of ordinary sewage filters The purification attained cannot be regarded as sufficient to meet the most exacting requirements, but still better results are expected from the past winter's campaign.

It is anticipated that the effluents may be made fit for re use in the factory, a practice which is already in operation in some cases, so that the daily discharge into the rivers will be reduced to a reasonable amount for treatment on biological filters

A biologist has been appointed to work under the direction of Prof Topley at the London School of Hygiene and Tropical Medicine, on the processes involved in the treatment of sewage by 'activated sludge' The solids of sewage after aeration become capable of flocculating colloidal matter and removing dissolved organic substances from further volumes of sewage In doing so the aerated solids, or 'activated sludge,' lose their activity, which can however, be restored by further aeration There is however, little exact knowledge of the process and it is yet uncertain whether it is physico chemical or the direct effect of micro organisms The de watering and the production of gas from sludge or sewage also engage the attention of the board

It is considered that a general biological and chemical survey of a typically polluted river would furnish information of general value as well as local information Such a survey should yield much new knowledge of river conditions generally of the interaction between the river and the various effluents —their direct or indirect effect upon the flora and fauna The Tees is suggested as a suitable watershed, the river having been under examination for several years and useful data already collected Undoubted damage has been done by pollution, but the nature of the damage and the various causes still offer a wide field for investigation

In all these matters the main part is played by micro organisms—the unpaid scavengers of every borough How they are best harnessed to destroy unwanted organic matter most efficiently, and even to break down naphthalene in coke oven effluents, provide outstanding problems

Compared with some continental countries, England is behindhand in providing facilities for the general study of freshwater biology and hydrology These subjects are no longer of academic interest only, for they enter into many economic problems within the Empire Mosquito control and tropical lake fishery investigations, for example, are in present need of information and recruits, which should normally come from an English freshwater biological laboratory, similar to the marine laboratory at Plymouth, where more than twenty visitors are at times working on varied researches during the university vacations That the Rivers Pollution Research Board will act as a valuable clearing house for information is assured We hope it may encourage the institution of a laboratory for post graduate workers near pools, lakes, and a river—a facility for which there is a present demand The study of aquatic life and of the breakdown of organic matter by micro organisms is not merely of domestic interest

The Board has also arranged for the investigation of the softening of water by the process in which it is allowed to trickle through beds of natural or artificial zeolite containing sodium in chemical combinations The sodium is displaced by the calcium and magnesium of the hard water, and the beds are finally rejuvenated by displacing the calcium and magnesium held by them with a solution of common salt The mode of action of the base exchanges is very imperfectly understood from the physico chemical point of view The process is in extensive use, but is little used by water supply authorities as yet

High-Voltage Alternators for the Grid

THE developments of engineering seem to be unending The manufacturer craves after mass production and standardisation, but his wishes are seldom gratified The progress of development sooner or later necessitates change One of these changes was pointed out by Sir Charles Parsons and Mr J Rosen in a paper read to the Institution of Electrical Engineers on Mar 21 They give in their paper reasons for thinking that very high voltage generators can be made which can be directly connected with the grid network without the necessity of using transformers The possibility of making very high voltage alternators has been known for many years So far back as 1905 the engineers of the Ganz company constructed several 30 000 volt alternators for use in the hydroelectric power station at Subiaco, 34 miles from Rome Credit must be given to the engineers for this early pioneering work, and the successful running of these machines show that they had overcome the difficulties of insulating these high voltages

Engineering history often illustrates the change of procedure brought about by new developments In the early days of marine propulsion, for example, the use of step up gearing between the prime mover and the propeller was a necessity When triple expansion reciprocating engines came into use it was found possible to operate without gearing For modern steam turbines and some types of Diesel engine speed reduction gears are now necessary Just as mechanical gear forms the link between the engine and the propeller so in electrical power distribution at high pressure the transformer has for many years been a necessary link between the generator and the network and also between the network and the lighting and motor load

Sir Charles Parsons and Mr Rosen propose to abolish the step up transformers by using very high voltage generators which can be connected directly with the mains

They point out that the continually increasing size of the generator units now make the conditions favourable to the introduction of these generators They consider the design of a 94 000 kilovolt ampere, 11,000 volt, three phase generator In this case the current at each terminal is about 4900 amperes Much space is required to accommodate the many cables mounted below the alternator terminals in a cable tunnel through the concrete With so many cables grouped together difficulties are experienced with the girders which reinforce the concrete The maximum output from the cables also is rarely obtained The authors show that not only are most of these difficulties overcome but considerable economies are also effected by using an alternator of a higher voltage If the pressure is increased to 33 kilovolts, the output current is reduced to 1640 amperes, and instead of six cables per phase only two are required

One great advantage of raising the pressure is the reduction in the cost of the leads and switchgear which it effects In very large units the enormous currents developed are very difficult to control and operation becomes almost impossible The General Electric Co of Schenectady when designing a 208,000 kilowatt unit for the State line station near Hammond, Ind , found it necessary to reduce the current This was done by raising the pressure from 18 to 22 kilovolts

Details are given by Sir Charles Parsons and Mr Rosen of the design of a 33,000 volt, 25,000 kilowatt alternator which has been working at the Brimsdown power station in north London since August 1928 A very novel feature in the design is the use of triple concentric mains for the armature conductors By this means they are able to reduce the maximum electric stresses to which the dielectric would otherwise be subjected This formation of conductor also is mechanically very strong The three conductors are called the bull inner, and outer ' respectively The bull conductors of each phase are connected in series, they are then connected with the 'inners' in series and finally with the outers The whole arrangement is connected in star and the star point is connected with the earth

The test results obtained with this machine were very satisfactory The shape of the voltage wave was practically the same as that of a sine curve The machine when running at its normal speed of 3000 revolutions per minute was suddenly short circuited The short circuit current was less than five times the normal full load current It seemed to function satisfactorily under these conditions the end conductors showing no sign of having moved mechanically The efficiency on a load of 25 kilowatts was 96 5 per cent Even when the load was so low as 10 kilowatts the efficiency was 93 5 per cent For the last six months it has operated continuously up to its maximum load at voltages varying from 34 to 35 kilovolts, and it has withstood without showing any sign of distress the sudden loads thrown on it when severe faults have developed on the large overhead and underground network to which it is coupled

The first step in the process of getting rid of the step up transformers connecting the generators to the grid network has been made The standard pressures of transmission in Great Britain are 33, 66, and 132 kilovolts Manufacturers can now make 33 kilovolt generators, and doubtless 66 kilovolt generators will soon be made In the meantime, however, these pressure generators can be advantageously used on 33 kilovolt circuits Although the authors in this paper confine themselves to high voltage generators, it is obvious that the ever increasing size of motors, motor generators, and synchronous condensers will enable them soon to be economically designed so as to be coupled directly to the network without the use of intermediate transformers Sir Charles Parsons and his associates are to be congratulated on having initiated a new and very promising development in electrical engineering

The New Acoustics [1]

RAYLEIGH S Theory of Sound, ' published more than fifty years ago, may be taken as representing the whole range of the physical acoustics of that period, and the much enlarged second edition, published eighteen years later, gave, in conjunction with Helmholtz's 'Sensations of Tone ' a fairly complete view of the acoustics of a generation ago Subsequent treatises have followed the classical methods thus established, and show little trace of the revolution which has occurred during the past decade in consequence of the influence of electrical theory and practice These changes have been stimulated by needs arising partly out of the War, but still more out of broadcasting

On the experimental side, much new apparatus of an electrical character has become available The

[1] Summary of presidential address delivered to the Physical Society Mar 22, 1929 by Dr W H Eccles F R S

condenser microphone enables sound to be converted into its equivalent electrical current with the minimum of distortion and, in conjunction with the triode amplifier, enables vibrations to be detected and measured which, though of audio frequency, are inaudibly weak The triode can also be used for the production of sounds the amplitude and frequency of which are widely variable and can be maintained very constant The electric filter circuit has provided a powerful method of purifying and sifting oscillations of mixed frequencies The conversion of sound into electrical oscillations enables the whole range of electrical methods of measurement to be used

On the theoretical side, the technique which has been developed for the study of impedance networks has been applied to the solution of acoustical problems For example, the squeaking of a slate pencil is analogous to electric relaxation phenomena, such as the flashing of a shunted neon lamp

Architectural acoustics has benefited by the availability of loud, filtered monotone sounds and distortionless sound detectors The decay of sound due to absorption in the walls of an auditorium, first studied by Sabine, has been accurately measured by electrical methods, with great advantages for the regulation of reverberation in buildings, both by architectural design and by the development of sound proof materials

In the realm of physiological acoustics, such interesting facts have emerged as that a change in intensity of a monotone must reach ten per cent to be noticeable Accurate results have also been obtained for the range of pressure and amplitude within which a sound must lie to be audible, and for the masking of one sound by another of different pitch

One practical outcome of these researches has been the development of public address apparatus, by means of which an orator can address an audience of a million persons Many problems of distortion have had to be solved in the working out of this apparently simple system, which comprises a microphone, amplifiers, and loud speakers The intensities of the sounds to be dealt with vary in the ratio of 1 to 1500 in the case of speech and 1 to 100,000 in the case of music; and it is found that if all the harmonics of a given sound be amplified equally, the resultant sound appears to be distorted, owing, presumably, to the non linear response of the ear

Conceptions and nomenclature developed in connexion with electrical impedance networks have been carried over into acoustics The 'motional impedance' of a telephone diaphragm was implicitly recognised in earlier works, but in the hands of Kennelly and Pierce, who introduced the nomenclature, Hahnemann, Hecht, Webster, and others, the representation in electrical terms of the inertia, resilience and energy dissipation in mechanical parts has yielded valuable results Thus, it has been found that the impedance of a horn approaches pure resistivity (yielding maximum efficiency) at frequencies above a lower cut off frequency which is very much lower for an exponential than for a conical horn The conception of motional impedance can be applied to clarify substantially the design of complicated electro acoustic combinations such as that which is constituted by a loud speaker a detailed example was given by the lecturer

In measuring the subjective loudness of sounds, telephone engineers have introduced the conception of the 800 cycle standard mile this corresponds to the difference in aural sensations derived from telephones at the beginning and end of a mile of standard cable at 800 ~, and roughly to a 25 per cent difference in power It has consequently been proposed that the increase ratio $10^{0 \cdot 1}$ or 1 259 of power should be standardised for all frequencies, this ratio being known as a 'transmission unit' Thus, if the power of an auditory stimulus were increased 1000 times, the sensation would increase by 30 transmission units Since pitch also increases according to the logarithm of frequency, the most human way of representing acoustical relations graphically is to plot transmission units against the logarithm of the frequency

The address concluded with a suggestion that the new acoustics should find a place in college courses and examination syllabuses C W H

Natural Hybrids in Plants

SINCE Darwin directed attention to the problem of the evolution of a species, there has been considerable interest in the extent to which the individuals of such a species form fertile offspring when crossed with other organisms not included in the species Obviously, if such attempts at hybridisation were ineffective under natural conditions or yielded infertile offspring, then the maintenance of the species as a distinct race was readily intelligible, however difficult it might be to understand how varieties crossing readily with one another had in course of time devolved into distinct species which had lost the power of interbreeding

During the recent discussion upon natural hybrids of plants at the Linnean Society of London on Feb 28, the president, Sir Sidney Harmer, and Mr M A C Hinton, pointed out that amongst the wild mammals, naturally occurring hybrids are almost unrecorded It will be remembered that Huxley always regarded this property of fertility within its ranks and failure to breed outside them as one of the most characteristic features of the natural species, and therefore as the outstanding feature which distinguished it from a race of cultivated animals or plants produced by artificial selection The latter is often as distinct in structure and form as many a good natural species, but continued to breed freely with other races within the same domesticated species

Darwin in the "Origin" clearly recognised that natural affinity, as expressed in a natural classification, included the sum of all characteristics of the organisms, including those connected with fertilisation mechanisms, so that natural affinity was usually an index to capacity to interbreed As a general rule, therefore, varieties crossed more freely than species, and species than genera, yet the diverse factors associated with reproduction in the organism varied from type to type so that some varieties failed to interbreed, whilst in other cases genera might yield intergeneric hybrids and species would only ripen seed if crossed by foreign pollen

Since the days when the significance of these natural hybrids to the study of evolution were grasped, our knowledge of their occurrence has considerably advanced, as was well illustrated by the discussion at the Linnean Society Dr A W Hill dealt with the New Zealand flora, in which some 290 groups of wild hybrids have now been noted, belonging to 42 families and 92 genera In some genera, as *Phormium*, which includes the New Zealand flax plant, these plants open up questions of great economic importance

A remarkable series of *Gaultheria* hybrids were exhibited by Dr Hill, which showed a gradual transition from *G oppositifolia* to *G antipoda* and *G rupestris*, and thence to *G perplexa*, also series between *G perplexa* and *antipoda* and *rupestris* and

antipoda The species *oppositifolia* and *rupestris* have a dry capsular fruit without fleshy calyx segments, in *antipoda* the calyx becomes thick and fleshy as the fruit ripens, whilst in *perplexa*, in addition, the fruit is a fleshy berry Most of these hybrid Gaultherias produce viable seeds Messrs E M Marsden-Jones and W B Turrill described genetical experiments and field observations on certain British genera They conclude that the polymorphism of such a genus as *Centaurea* owes much to hybridisation, which is thus one, but only one, of the factors in organic evolution

Prof C E Moss described some of the natural hybrids of *Clematis*, *Anemone*, and *Gerbera* occurring in the Transvaal The study of such natural hybrids leads Prof Moss to the conclusion that bigeneric hybrids occur in Nature and may be fertile Similarly, fertile hybrids occur between well defined species Hybrids of either of these classes are not common, they are often striking plants and are easily detected On the other hand, between closely allied species, fertile hybrids may readily occur in abundance and may give rise to that polymorphism in some groups of species which is so perplexing to the systematist Prof Moss stated that he had met no case of the occurrence of natural hybrids in the field, which led him to think that natural hybrids gave rise to species

Dr Lloyd Praeger pointed out that, of some fifty species of *Sempervivum* in the Canary Islands, some thirty five were known to hybridise, amongst the hybrid offspring barrenness is very general Dr O Stapf, speaking from the point of view of a systematist, agreed that hybrids are abundant in many plant families in Nature, and thought that the isolation of a hybrid progeny may lead to the appearance of a new species

Dr J P Lotsy is the champion of the theory that hybridisation is the main instrument of species evolution, and Dr C L Huskins pointed out that this theory includes the possibility of 'hybridisation' within a single nucleus Obviously the problem will in the future be taken further as this wealth of natural hybrid material is submitted to cytological examination, the data as yet available from such cytological work were utilised by Dr E J Collins in his contribution to the discussion

University and Educational Intelligence

Applications are invited by the London County Council for two Robert Blair fellowships, each of the annual value of £450, tenable for one year The fellowships are for advanced study or research in applied science and technology, and are tenable in the Dominions, the United States or other foreign countries Further particulars and application forms (T 3)/300 may be obtained from the Education Officer (T 3), The County Hall, S E 1 The completed forms must be returned by June 18

The St Andrews Committee for the Training of Teachers is organising a summer school, to be held at the United College, St Andrews, on July 8–26 Courses of lectures on modern advances in physical science, by Prof H Stanley Allen, on the teaching of physics and chemistry, by Messrs J W Bispham and R H Dickinson, and on rural science, by Mr M R Gillanders, are included in the programme Particulars can be obtained from the Director of Studies, Training College, Park Place, Dundee, applications to attend must be sent in not later than May 1

The recently published Annual Report of the Carnegie Trust for the Universities of Scotland is of more than ordinary interest, including, as it does, statements showing the working during the five years 1923–28 of the Trust's various schemes for encouraging the pursuit of scientific research Under the scheme of postgraduate study and research, which has been in operation for twenty five years, 478 awards were made in the quinquennium at a cost of £51,047 Closely associated with this scheme is the provision made by the Trust since 1923–24 for 'teaching fellowships' for university lecturers and assistants, who hold them subject to the condition of devoting not less than half their time to research Forty one such fellows have been at work at a cost to the Trust of £20,023 Detailed reports, classified under subject headings, of the work done under these schemes and of researches, subsidised by the Trust, in the laboratory of the Royal College of Physicians, cover about eighty pages Of more general interest are the reviews by the Trust's expert advisers Reviewing the work done in (1) physics and chemistry and (2) biology and medicine, Profs Arthur Smithells and J T Wilson both comment on the increasing demand for scientific assistance in industrial concerns There is a greater demand for trained chemists than has ever been known in Great Britain, and the lure of industrial appointments has led in many instances to the curtailment of the period of tenure of fellowships and scholarships The Trust's research schemes function, says Prof Wilson, as a sort of unofficial Scottish staff college for research, from which are recruited personnel not only for university staffs, but also for staffs of other public laboratories and institutions They cost the Trust £82,700 during the quinquennium Its grants to universities and extra mural institutions for 1925–30 amount to £231,225, assistance to Scottish students in the payment of university class fees in the one year 1927–28 amounted to £57,772

The University of Leeds gives, in its report for 1927–28, an account of important additions, costing upwards of £150,000, to its buildings Increased accommodation was thus provided for the medical, dental, mining, and textile departments and for the residence of men and women students Plans were also approved for new buildings for the physics and chemistry departments Statistical tables appended to the report show that during the five years 1923–28 the number of full time day students has continuously declined from 1475 to 1296 It is, however, still nearly twice the number (663) in 1913–14 The decrease in 1927–28, compared with the preceding year, was chiefly among men students in the faculties of technology and medicine, and women students in the faculty of arts Facilities for research were substantially increased during the year, notably by (1) the acquisition of an estate suitable for the pursuit of cancer research, and including a convenient residence for the professor of experimental pathology, (2) a grant by the Clothworkers' Company of £3000 a year for four years, enabling the University to appoint a lecturer in textile physics with a research assistant and to award eight fellowships for investigators in the textile industries and dyeing departments, (3) the recognition of researches conducted in the laboratories at Torridon of the British Research Association for the Woollen and Worsted Industries as qualifying for the University's research degrees It has been decided to publish annually, in a separate pamphlet, short summaries of unpublished research work and references to published work accepted for higher degrees, and to include in the pamphlet the list, hitherto published as an appendix to the annual general report, of works, original papers, etc, by members of the University Among gifts to the University during the year was one by Messrs Briggs, Son and Co, of a scholarship of £150 a year for five years, tenable in the Mining Department

Calendar of Patent Records

April 14, 1720 —The 'stoving' process of seasoning timber for shipbuilding—in which the timber is heated in wet sand—was the invention of John Cumberland, whose patent is dated April 14, 1720 The process, which was reported by the Admiralty to be much superior to the old method of charring that it displaced, was used in the Royal dockyards for some years, an allowance of £200 a year being guaranteed to the inventor An application for a prolongation of the grant was dismissed

April 17, 1882 —The 'telpher' system of transportation—in which goods are carried by electrically operated and automatically controlled trolleys travelling on a mono rail—was the invention of Prof Fleeming Jenkin, his patent being dated April 17, 1882 The first commercial installation in England was opened in 1885 for carrying clay from the pits at Glynde in Sussex to the railway

April 18, 1707 —On April 18, 1707, there was granted to the first Abraham Darby a patent for his invention of "casting iron bellied potts and other iron bellied ware in sand only without loam or clay," which greatly increased the use of iron for founding purposes Previous to this invention, such articles were only made in the more costly brass, iron castings being confined to the production of simpler articles such as fire backs and grave slabs Abraham Darby's name is an honoured one in the history of the iron industry, for it was he who, about 1710, first discovered and put into practice a satisfactory process for the smelting of iron with coke

April 18, 1818 —The omnibus dates from the French patent granted to De Berckem of Paris on April 18, 1818, for what he called a 'Parisienne,' carrying eighteen persons A previous attempt—with which Blaise Pascal was associated—had been made to run public vehicles of this kind in Paris, but it was not successful and was soon abandoned

April 18, 1838 —William Barnett's patent, dated April 18, 1838, is an important milestone in the history of the gas engine, for it was in this that the advantages of compressing the combustible mixture before igniting it were first pointed out In Barnett's engine the air and gas were compressed separately and were mixed in the cylinder at the beginning of each stroke A special ignition cock, which remained long in use, was also a feature of the invention

April 18, 1885 —One of the early suggestions for utilising the principle of the gyroscope to replace that of the magnetic needle in the mariner's compass was the invention of two Dutchmen Gerardus van den Bos and Barend Janse, whose German patent was applied for on April 18, 1885

April 19, 1758 —The achromatic telescope of John Dollond was patented on April 19, 1758 No action seems to have been taken by the Privy Council on a petition signed by most of the instrument makers of London, alleging that object glasses in accordance with Dollond's patent had been made and publicly sold before the date of the grant and praying for the revocation of the patent, and the patent was afterwards upheld in the Courts in an action for infringement But there seems to be little doubt that Chester Moor Hall was the first inventor

On the same day, April 19, 1758, there was granted to Jedediah Strutt a patent for the rib stitch hosiery frame, which was the first important modification of Lee's stocking frame Strutt invented the rib stitch machine for his hosier brother in law, William Woollatt, and the two started what became very successful works at Derby and Nottingham

Societies and Academies

LONDON

Mineralogical Society, Mar 19 —**A W Groves** and **A E Mourant** Inclusions in the apatites of some igneous rocks Apatite crystals with dark cores of inclusions have been observed among the heavy minerals of some English sedimentary rocks, but there are few records of such apatites in igneous rocks The authors record several such occurrences in granites and in volcanic rocks from Normandy, Jersey, and Brittany Five different types are distinguished in the granite of northern Brittany alone In one type with a definitely pleochroic core the inclusions appear to consist of biotite or chlorite, but in other types it has not been possible to determine their nature —**L A Narayana Iyer** Calc gneisses and cordierite sillimanite gneisses of Coimbatore, Madras Pres, and similar occurrences in India The paper dealt with a suite of crystalline gneisses in the ancient Archæan complex of India of Dharwar age (Huronian), consisting of the above two facies which are in close association Similar suites of rock occur in different parts of India, forming a definite stratigraphic horizon The author considers their formation as due to thermal or 'infra plutonic' metamorphism followed or accompanied by regional or dynamo thermal metamorphism of pelitic schists and calcareous sediments —**F A Bannister** A relation between the density and refractive index of silicate glasses with application to the determination of imitation gem stones The study of simple glass families leads to a relation between the refractive index and density which can be applied in a modified form to the determination of imitation gem stones $(n-N)/(d-D)$ where N and D are the refractive index and density of silica glass, is plotted against n by a simple graphical method, whereupon the various imitations separate into groups, the members comprising any one group are chemically similar Doubtful cases can be solved by measuring in addition the relative dispersion —**H E Buckley** The crystallisation of potash alum The author described the results of experiments on the differences of crystal habit obtained under varying conditions of cooling and evaporation, and in the presence of various substances in solution such as strong acids, $AlCl_3$, FCl_3, amyl alcohol, Bismarck Brown, etc

PARIS

Academy of Sciences, Mar 4 —**A Deslandres** Simple relations between the most intense and highest radiations of the chemical elements in the photosphere of the sun In previous communications it was shown that the frequencies of the highest and most brilliant lines of the sun were multiples of a constant d_1, 1062 5 Additional data showing the importance of this constant are given —**Charles Moureu, Charles Dufraisse, and Léon Enderlin** Researches on rubrene The action of acids The liberation of iodine from hydriodic acid by rubrene, with decolorisation of the hydrocarbon, has been studied in detail Except possibly in ether solution, there is no evidence of any hydrogenation the colourless hydrocarbon produced appears to be isomeric with rubrene —**J Favard** Problems of extremums relative to convex curves —**Maurice Janet** The ratio of the mean values of the squares of two differentials of consecutive order —**Mandelbrojt** How several theorems of Taylor's series can be transformed into Dirichlet's series —**J Delsarte** Symmetroid nuclei —**L Ahlfors** The number of asymptotic values for an integral function of finite order —**M Lavrentieff** A problem of P Montel —**Gr C Moisil** Functional groups —D

Rosenthal Assemblages connected by lateral bands tested in extension and in compression —**Maria Bossolasco** Tho ellipticity of the terrestrial equator —**Foch** The maintenance of the vibrations of a fluid column by change in the regime of flow From Reynolds's definition of the critical velocity an equation is derived which has been applied to the cases of vibrating flames, the chemical harmonicon, and notes emitted by certain hot water systems —**T Pecsalski and J Chichocki** The thermionic emission of copper tubes filled with salts —**J Peltier** The magnetic testing of the shafts of machines —**R Coustal and F Prevet** A new method of preparing phosphorescent zinc sulphide Zinc (in impalpable powder) and sulphur are heated together, with or without the addition of foreign substances The reaction is explosive and must be controlled by reducing the proportion of zinc —**R de Mallemann** The theory of optical activity in a homogeneous medium —**René Delaplace** Some chemical phenomena connected with the contraction of hydrogen in discharge tubes Discharges through tubes of Pyrex glass, not fitted with taps or ground glass connexions, produce measurable amounts of carbon monoxide and methene These may be attributed to the dissociation of the glass under the influence of radiations omitted by the tube —**Raymond Delaby and Pierre Dubois** The preparation of allyl alcohol The method described permits of a yield of 435 grams of allyl alcohol per kilogram of glycerol —**Mlles Jeanne Lévy and Frajda Gombinska** The dehydration of some symmetrically substituted α glycols and the isomerisation of the corresponding ethylene oxides The influence of the relative affinitary capacities of the cyclic and acyclic radicals —**A Seyewetz and J Blanc** The fluorescence of colouring matters in Wood's light The principal dyes of each class have been submitted to Wood's light in powder, in solution, and on fibres, in order to see whether they would present any fluorescence sufficiently characteristic for use in analysis Preliminary results are given —**Assar Hadding and René van Rubel** The structure of the crystalline uraninite of Katanga (Belgian Congo) The X ray method of P Debye has been applied to Katanga uraninite Its crystalline network is that of a face centred tube —**P Fallot** The date of the latest orogenic phenomena in the sub Betic and Betic zones at the height of Caravaca —**Jean Lacoste** The extension of the Cretaceous in the southern region of the western Rif —**Edouard Roch** New observations on the Stephanian of western Morocco —**Ch Maurain and E Salles** Atmospheric ionisation —**Albert Nodon** Researches on electromagnetic perturbations, seismic and solar The results obtained at the Santiago Observatory (Chile) confirm work previously published by the author, and show that close relations exist between electromagnetic, seismic, telluric, atmospheric, and solar phenomena It is possible from the indications of the magnetograph to predict earthquakes some hours in advance —**C I Popesco** The influence of grafting on the development of some Papilionaceæ —**Mme L Randoin and Mlle A Michaux** The comparative variations of the proportion of water in the blood and of the globular resistance in the normal guinea pig and in the guinea pig submitted to a regime deprived of the antiscorbutic vitamin —**Mme M L Verrier** The biology and peculiarities of the respiratory apparatus of an isopod from the Sahara, *Hemilepistus Reaumuri* —**J Magrou, Mme M Magrou, and Mlle F Choucroun** The action at a distance of *Bacterium tumefaciens* on the development of the egg of the sea urchin New experiments —**E Roubaud** Autogenous cycle of waiting and hidden active winter generations in the common mosquito *Culex pipiens* can have two different biological methods of adaptation to the winter In one, well known, the females hibernate at low temperatures, in the other, described in the present communication, both sexes survive if the temperature is maintained above 20° C in presence of water Reproduction is continuous during the winter without food being taken —**Marcel Labbé, F Nepveux, and Hejda** The ammonia of human blood in normal and pathological conditions In cases of jaundice, cirrhosis of the liver, and diabetes, the proportion of ammonia in the blood varies very slightly from the normal the amount is increased to a marked extent in pulmonary tuberculosis —**H Bierry** Biochemical researches on the specificity and transformations of the proteids of the blood plasma —**L Hugounenq and E Couture** The photochemical action of sterols of various origins —**A Dorier** *Gordius* as a parasite of myriapods —**A and R Sartory, Marcel and Jacques Meyer** Contribution to the study of tho mycetones A new case of actinomycosis with yellow pustules

ROME

Royal National Academy of the Lincei, Dec 16 —**T Levi-Civitá** Addition to the note on the motion of a body of variable mass —**Gino Fano** Congruences Ω_0 of rational curves, and Cremonian transformations inherent in a linear complex —**A Russo** Nuclear divisions in *Cryptochilum echini* Mps In this organism the processes of nuclear division are dependent on the category of the individuals to which the nuclei belong, since the nuclei of one category (A) divide by mitosis, and those of another (B) by amitosis These two categories being distinguished by different quantities of nuclear substance, with which correspond particular activities of tho whole individual, it appears that the special division of the nucleus is determined by internal factors which regulate the process —**L A Herrera** Further investigations on the imitation of organic forms with albumin Structures obtained by means of egg albumin and closely resembling *Croococcus, Botrydina vulgaris, Desmidium Grevilli, Bulbochæte, Vaucheria,* and *Nitella flexilis,* are illustrated —**U Cassina** The conception of limits A short, elementary account is given of the results of the author's historical and critical investigation into the conceptions expressed by the term 'limit' —**L Fantappié** Functional operators and the calculus of infinite matrices in the theory of quanta (1) —**M Picone** Demonstration of a theorem of analysis, of which use is made in plane physics —**G Supino** Certain limitations valid for derivates of a harmonic function —**L Toscano** Reciprocal matrix equations —**G Vranceanu** Second fundamental quadratic form of an anolonomious variety and its applications —**V Glivenko** The law of high numbers in functional spaces —**A de Mira Fernandes** Isoclinic transports and associated directions —**F Lamberti** A third cardinal equation in the dynamies of material systems —**E Gugino** The extension to continuous motion of the Lagrange Bertrand theorem relating to impulsive motion —**G Silva** The definition of normal gravity —**E Benedetti** Experiments on the amplification and detection of bio electric currents by means of thermionic valves (2) The photographic registration of the curves of the amplified currents Use is made of a ray reflected by a mirror set in motion by an electrodynamic complex similar to those used to move the membranes of 'loud speakers' —**Clara Forti** The action of vapours of ethyl and methyl alcohols, ethyl ether, and chloroform, and of lighting gas on leucocytes isolated from the organism The vapour evolved by minimum quantities (0 1 0 5 c c) of ethyl or methyl alcohol, ether or chloroform suffices to paralyse

the amœboid activity of the leucocytes of toad blood within a few minutes The action of illuminating gas is slow and results first in an increase in the vivacity of movement of the leucocytes, but later to a gradual retardation of the motion, which is completely arrested after exposure to the gas for eight or nine hours These effects may be either transient or permanent, according to the duration of action of the reagent —**G Galatà** Investigations on the circulatory effects of increases in the atrial pressure — **R Margaria** and **E Sapegno** Blood mass, red corpuscles, and hæmoglobin, in acclimatised individuals, in the mountains and on the plain The observations described were made on ten individuals, first, in August 1927 at Col d Olen (altitude 2901 metres), and, secondly, in the autumn and winter of 1927–28 at Turin, the temperatures in both cases being 10° 13° At Col d Olen, increases in the number of red corpuscles and in the hæmoglobin content of the blood were invariably found The extents of these increases varied markedly in different individuals, the mean values being 12 8 per cent for the corpuscles and about 4 per cent for the hæmoglobin There is, therefore, a diminution in the hæmoglobin content of the red corpuscles, which may be the expression of the immission into circulation of young red corpuscles less rich in hæmoglobin—a phenomenon perfectly analogous to that observed after blood letting As regards the mass of the blood, determined by Haldane and Smith's method, the variations found amounted only to about 5 per cent, which corresponds with the limit of error for a single experiment, there is a mean increase of 1 8 per cent, which indicates that there is a slight increase in the mass of the blood following a sojourn of 15 25 days in the mountains, this being possibly due to the improved hygienic conditions —**R Grandori** Embryological studies on polyvoltine races of the mulberry *Bombyx*

VIENNA

Academy of Sciences, Jan 10 **R Holzapfel** Results of radiation and polarisation experiments on the Hochobir in the summer of 1927 at an altitude of 2040 metres —**E Philippi** and **E Galter** The action of ammonia and amines on the esters of unsaturated acids —**E Philippi** Memoranda for the preparation of some aliphatic unsaturated acids and esters —**F Hernler** The three isomeric tolyl 1 dimethyl 3, 5 triazole 1,2,4 and some of their salts — **G Grekowitz** A meningitis producer from the Pasteurella group In three cases of middle ear discharge a germ was isolated, a small coccus like bacterium easily stained with the usual aniline dyes, but not with Gram A faint smell is characteristic of the colonies Gelatine was not liquefied Milk sugar and mannite were neither acidified nor fermented — **F Werner** Scientific results of a journey of exploration to Western Algeria and Morocco Snakes, lizards, and scorpions are recorded —**E Bersa** The culture and nutrition physiology of the genus *Pilobolus* Easily cultivated on horse dung decoction agar Of nitrogen sources leucine and peptone, of carbon sources xylan, gum arabic, galactose, starch do best A wheat straw extract with peptone and agar proved a good culture medium, also Liebig extract agar peptone —**K Menger** On the sum of regular curves —**K Przibram** Coloration of rock salt by radium rays and re crystallisation Apparently rock salt on compression undergoes re crystallisation, the more rapid when pressure is greater After such re crystallisation the blue colour and the capacity of turning blue have vanished —**O Watzl, K Swoboda,** and **R Singer** Report on a botanical and geological expedition in the Caucasus The Caucasian Alpine Society supplied intelligence The Dongusorun glacier pass (3200 metres) was difficult The Chodschal mountain group (3309 metres) was examined Valleys choked with thick primitive forest were difficult to penetrate, the few paths being mostly on slopes above the tree limit Collections were made of Rhododendron and other shrubs and of the very rich fungus flora

Lord Haldane in Science and Education

THE autobiography of Lord Haldane recently published throws a flood of light on several questions of scientific and educational interest Mr Sidney Webb once expressed the view that men of science who had entered the field of politics had not as a rule distinguished themselves in Parliament, a judgment which, with commendable impartiality, he extended to historians and economists This view was challenged at the time Playfair and Lubbock, it was suggested, had rendered valuable services as members of Parliament, and Huxley as a member of the first London School Board Ought we not to regard these instances as exceptions proving the rule ? To the man of science, groping with his taper along the rugged pathway towards truth, the eclectic arts, the rhetorical triumphs—and at times the over weening confidence—of the politicians make no strong appeal

Whatever view may be taken on this question, it will be agreed that politicians who concern themselves with the promotion of science and education are fulfilling a useful rôle in our national economy With increasing specialisation and increasing demands on both public and private funds for the promotion of research, science needs sympathetic interpreters, missionaries—propagandists, if you will—to whose warnings and exhortations the public will listen with due respect Haldane, as a man of outstanding intellect and untiring industry, as a politician who attained the highest offices in the State, as an active participator in the gravest decision which our nation was ever called upon to make, had many of the qualifications for this essential work That he discharged his duty with conviction and disinterestedness, the reader of the autobiography will admit His success was partial, as he himself admits A man is a hero to his autobiographer, one would suppose, but Haldane writes candidly in his final chapter entitled " Looking Backwards " " I have no sense of success on any very large scale in things achieved But I have the sense of having worked and of having found happiness in doing so " That guerdon is not withheld from the humblest of the world's workers " One touch of Nature makes the whole world kin " Haldane's posthumous candour should induce a tolerance which was not shown by the public during his life

Asked by Cecil Rhodes, " What have you done in your life ? " Haldane replied, " I got the London University Bill through the Houses of Parliament ", on which Rhodes remarked, " That seems to be a very curious thing " The reference was to the

Bill of 1898, introduced by the Conservative Government to transform the examining university into a teaching university. Haldane was justified in his proud boast. Politically, the subject was thorny; the supporters of the old system of impartial examinations exercised powerful political influence, and the proposed scheme of re-constitution bore many of the scars of compromise. Unless some politician of strength and honesty of purpose had espoused the cause, we can well believe that the reform would never have been accomplished. The tragedy was that Haldane so soon showed a sort of Red Queen animosity towards his own offspring. We must await the publication of further biographies and autobiographies before this mystery is fully explained.

An interesting chapter in the history of higher education relates to the breaking up of the old Victoria University, the federal university seated at Manchester. In this important development, Haldane took an active part. Birmingham, under the influence of Joseph Chamberlain, had established the first civic university in 1900. Soon afterwards, Liverpool petitioned for a separate university. "Manchester somewhat half-heartedly supported the prayer of Liverpool, but Leeds strongly opposed it, and was backed by a number of persons who were eminent in the field of higher education in those days." The hearing of the petition by a Committee of the Privy Council lasted three days. Haldane was precluded from acting as counsel for Liverpool, as he had been appointed a member of the Privy Council a short time before the hearing; but he was able to plead the cause as a witness. His arguments for civic and educational personality were accepted. The Committee recommended the grant of university charters to Liverpool and Manchester, and the grant of a charter to the University of Leeds followed a year later. Haldane remarks with truth: "It has always seemed to me that the decision of the Government as advised by the Privy Council in 1903 was a step of the first importance in the history of higher education." But, as he says, little notice was taken of the matter at the time by the public or by writers about English education.

The decision gave a deathblow to the federal idea in higher education in its application to our great cities and started the growth to full university stature of institutions such as the Universities of Sheffield (chartered in 1905), Bristol (1909), of which Haldane was the first Chancellor, and Reading (1926). Several university colleges are in the later stages of adolescence, including those at Nottingham, Exeter, Hull, Southampton. No one would now be found to question the wisdom of the policy advocated by Haldane in this matter.

Haldane's work in the promotion of science and technology at South Kensington is well known. The entry in the index under the author's name states summarily—"Founds the Imperial College of Science and Technology." King Edward VII inspired this great development in a spirit of filial piety, and Haldane was brought into close personal touch with his Sovereign. Haldane's original scheme of a 'London Charlottenburg' suffered a sea-change. No doubt he was offered a surfeit of 'expert' advice. Curiously, Haldane's investigations in Germany had impressed him unfavourably with the separation existing there between the universities and the technical colleges, and he tells us he decided to press for the application of a different principle in London. "The new college was to be fashioned so as to be brought as quickly as possible into a re-constituted University of London." There must be some lapse of memory here, for, in the letter which Lord Rosebery as Chancellor of the University of London addressed to the London County Council in 1903 to explain the Charlottenburg scheme—the letter, we may safely presume, was drafted by Haldane—there was no reference to the question of re-constituting the University and this issue did not arise until some years later. Lord Rosebery, indeed, expressed the hope that it might be possible to follow up the Charlottenburg scheme "by taking further steps towards developing the University in such a fashion as to make it worthy to be the University of the metropolis of the Empire"—but the reference here is obviously to other educational rather than to constitutional developments.

Exasperating delays occurred and an unhappy controversy arose as to the relations of the Imperial College with the University, a controversy which has not yet been brought to a final conclusion. It led directly to the appointment of the abortive Royal Commission on University Education in London over which Haldane presided. The autobiography does not indicate that Haldane derived much satisfaction from his attempt to re-constitute the University for a second time. He is singularly reticent on the whole subject. Nevertheless, he lived long enough to see the last stages of a re-constitution of the University which, the friends of the University hope, will remove some of the defects of the earlier compromise; and he must have watched with pleasure the recent purchase of the Blooms-

bury site by the University, aided by the Rockefeller Foundation, a site he had ineffectively recommended so long ago as 1912 for the great Imperial university he wished to see established in London

Was science able to offer any return for all this effort and goodwill? We learn with pleasure from the autobiography that Haldane benefited from a great discovery in a university laboratory He was a sufferer from diabetes and was treated in the first attack by a rigid diet, "the only palliative known in those pre insulin days" Banting's discovery came at a happy moment, for Haldane would not have been able to count on good health without the discovery of insulin He arranged to have an injection in his arm every morning, and this served admirably, he tells us, taking the place of the pan creatic secretion of the 'Islands of Langerhans' Thus was prolonged a life which had rendered great services to the cause of science and had sounded the full gamut of human thought, emotion, and—may we not add, notwithstanding autobiographical dif fidence—success, achievement

A Neglected Genius

The Collected Scientific Papers of John James Waterston Edited, with a Biography, by Dr J S Haldane Pp lxviii + 709 + 5 plates (Edinburgh and London Oliver and Boyd, 1928) 25s net

IN 1892 the late Lord Rayleigh rescued from ob livion in the archives of the Royal Society a remarkable paper by John James Waterston which had been written in 1845 but had failed to obtain the approval of the Society, and had, therefore, not been printed in the *Proceedings* So completely has his work been ignored that it will probably come as a surprise to the majority that his writings (published and hitherto unpublished), which have been col lected and published by Dr J S Haldane, extend to more than seven hundred pages

Lord Rayleigh did ample justice to the 1845 paper on the physics of media that consist of per fectly elastic molecules in a state of motion Con cerning it he wrote "What strikes one most is the marvellous courage with which he attacked ques tions, some of which even now present serious diffi culties Waterston was the first to introduce into the theory the conception that heat and tem perature are to be measured by *vis viva* In the second section the great feature is the statement that in mixed media the mean square molecular velocity is inversely proportional to the specific weight of the molecules The proof which Waterston gave is doubtless not satisfactory, but the same may be said of that advanced by Maxwell fifteen years later" Boyle's law, Charles's law, Avogadro's law, and Graham's law of diffusion were all placed on a dynamical footing in this paper The causes which contributed to it being denied publication in 1845 are difficult to find At the present time it suffers from having been superseded in style and argument by the work of successors When written, it apparently suffered from being in advance of its time Joule's work on the dynamical nature of heat had been in part published, but the theory of conservation of energy was not authoritatively accepted until about six years later Even so late as 1848, Thomson (Lord Kelvin) wrote "The conversion of heat (or caloric) into mechanical effect is probably im possible, certainly undiscovered In actual engines for obtaining mechanical effect through the agency of heat, we must consequently look for the source of power, not on any absorption and conversion, but merely in a transmission of heat"

Who was the man whose scientific insight drew from Lord Rayleigh such high praise? In answer, Dr Haldane prefaces his collection by a short bio graphy His grandfather was founder of an im portant (still existing) firm of manufacturers of seal ing wax and other stationery, his grandmother was a niece of Robert Sandeman, a well known re ligious leader and founder of the body known as Sandemanians—to which Michael Faraday and his blacksmith father belonged—and sister of George Sandeman, who was founder of the well known firm of port wine merchants

Waterston himself went from school to the Uni versity of Edinburgh and studied mathematics and physics under Sir John Leslie, and was medallist of his year in Leslie's class He also attended lectures on anatomy and surgery—probably drawn to these subjects by his father's and his own interest in phrenology His first published paper was written in his student days when he was nineteen years of age (*Phil Mag*, 1831) It was an attempt to explain gravitation on dynamical principles It is interesting, because in it there is the germ of the ideas which he developed afterwards in his more important paper No further publication occurred until 1843, when an anonymous volume appeared entitled "Thoughts on Mental Functions" Here he sought to study metaphysics as a branch of the physiology of the nervous system Dr Haldane remarks "The book is a very acute essay, far ahead of its time The idea which guided him

was that human behaviour can only express itself in material changes which must, in so far as they are intelligible, be dependent on previous material changes "

In the interim Waterston had become a pupil of James Walker, F R S, a leading civil engineer and president of the Institution of Civil Engineers, and was employed in connexion with the rapidly developing railway system of England He contributed to the Institution a paper on a graphical method of estimating the earthwork in embankments and cuttings He felt, however, that his heart was in pure science and he obtained a post in the Hydrographer's Department of the Admiralty under Captain (afterwards Admiral) Beaufort, who encouraged his scientific ambitions, and later obtained for him the post of naval instructor at Bombay to the East India Company Cadets He held the post, except for a brief period, until 1857, when he returned to Edinburgh, where after some changes he ultimately settled down and remained until his death in 1883

Various papers were submitted by Waterston to different societies and not all of them were accepted, this seems to have embittered him His brother wrote of him " He showed a restlessness and dislike at the mention of scientific men, except Faraday, and he used very strong language in respect to some who bulk largely in public estimation " Dr Haldane surmises that his real antagonism did not arise from the non publication of his papers, but that he was critical of the leading physicists of his time, especially in regard to their thermodynamic reasoning The chief support brought forward for this surmise is the mention in his will of an unpublished manuscript, but as this manuscript was never found, it is rather idle to speculate as to what the subject matter of it might have been The reviewer finds it very difficult to follow Dr Haldane's argument in the pages he devotes to this question Quite certainly there is nothing in Waterston's published writings to justify attributing to him the views which his biographer puts forward

It is unnecessary to dwell on this aspect of Waterston's life He succeeded in getting papers published after his return, and there are many interesting questions dealt with by him In 1858 (*Phil Mag*) he describes experiments on capillarity The argument he kept in view is that if the capillarity of a liquid is the exhibition of part of the cohesive force of the superficial stratum of molecules, numerical relations with the latent heat of its vapour ought to be demonstrable The paper needs to be translated into modern language, but it is sound in idea It may be recalled that Dupré later (1886) developed a similar question, and in recent years E T Whittaker has displayed the close parallelism that exists between surface *energy* and the internal latent heat of evaporation Waterston made a large number of experiments to bring out the connexion, and he deduced, for example, $1\ 45 \times 10^8$ as the number of layers of molecules in one inch in the case of liquid alcohol

Again, Waterston describes a number of experiments on the transition (that is, critical) point of liquids in sealed tubes after the manner of Cagniard de la Tour The tubes were filled to different amounts with the same liquid, and he found the densities of the liquid and vapour when the liquid state terminates He found that the cup shape of the upper surface of the liquid, caused by its capillarity, ceased at a temperature considerably under the point of transition and while the densities of liquid and vapour were very different These observations suggest Prof Callendar's recent experiments on steam (*Proc Roy Soc*, Sept 1928), where about six degrees' interval is found between the two temperatures—the meniscus disappearing when the density of the vapour is only 0 6 of that of the liquid Waterston further claims to have observed that between these temperatures the surface became of ' a sugar loaf aspect,' that is, convex upwards He argues from the data that the rate at which the latent heat diminishes with rise in temperature must augment with the temperature, otherwise the critical point would be much higher than it is He observes that Regnault's curve for the latent heat of steam is discontinuous at 100° C, this is now a well recognised fact

Waterston put forward views on chemistry of which Prof McLeod has said that they " shadow forth many of the ideas of modern chemistry which have been adopted since 1845 "

Altogether, from the historical point of view, it is a good thing that Dr Haldane has done in editing these papers Crude they may seem to day in many respects, but " nothing awakes on its hundredth year without both looking (and feeling) queer ", and it is almost a century since Waterston's first paper appeared What he did, he achieved by very simple means, and modern progress has demonstrated that often elaborate means are essential so that his work was really pioneer work We may sum up by again quoting Lord Rayleigh " To say that he was not always successful is only to deny his claim [not made by him self] to rank among the very foremost theorists of all ages "

A Biologist as Ethnologist.

L'Industrie des pêches au Cameroun Par Dr Théodore Monod (Commissariat de la République Française au Cameroun, Mission Monod (1925–1926) Première partie, Généralités) Pp 509 + 25 planches (Paris Société d'Éditions Géographiques, Maritimes et Coloniales, 1928) 90 francs

RENAISSANCE of interest and pride in their colonial possessions are outstanding and most satisfactory features among the French of to day Prior to the War few Frenchmen went abroad, apart from Algeria, as colonists and planters, and, with some brilliant exceptions, the officials sent overseas were men of inferior quality, of whom their political party or their departmental chiefs were anxious to be quit Their salaries were often mere pittances, and their numbers, judged by the British standard, out of all proportion to real requirements , the sum total of their salaries was frequently excessive as compared with the revenue of their particular colony and a distinct impediment to development and progress Bureaucracy strangled enterprise even among their own countrymen, and French colonial administration was a synonym for inefficiency and red tape

To day much of this is changed A superior class of official is in evidence , better class families in France no longer frown upon a colonial life as a career for their more adventurous sons The Colonial Administration at headquarters is correspondingly enlightened and has had the wisdom to obtain the co operation of the scientific staff of the National Museum of Natural History in their efforts to develop colonial resources The outcome has been the establishment of the Laboratoire des Pêches et Productions Coloniales, under the able direction of Prof A Gruvel, nothing quite comparable with this very useful institution exists in Britain, though by one means or another the needs of the British colonies in this respect do get fairly well met through the willing co operation of various scientific and technical institutions

So far as British West African colonies are concerned, no work has been published comparable with the fine monograph by Dr Théodore Monod upon the fishing industry of the Cameroons, of which the first volume has recently appeared. A bulky tome, it gives in great detail a vast mass of information, technical, ethnological, and linguistic, touching the existing fisheries of the various hydrographic regions into which the territory is divided—the coastal, the riverine, and the lacustrine The present volume deals mainly with the technical and economic aspects, the next will contain the systematic reports of specialists upon the scientific collections made during the various tours The investigation carried out by M Monod, the delegate of the Colonial Fishery Laboratory, lasted rather less than one year , the results reflect the greatest credit on his energy , their presentation is on the whole admirable, but suffers, alas ! from the absence of any index or detailed table of contents Comparative references in consequence are made with difficulty, and the trouble is accentuated by lack of sufficient correlation between the text and the numerous illustrative line figures, charts, and diagrams

The facts recorded are probably of even greater value and interest to the ethnologist than to the fishery expert, and the lack of index is a serious handicap when comparing the methods and appliances of the various tribes The extraordinary variety of the fishing devices in daily use and the complexity of several reveal the intellect of certain tribes as much more versatile and adaptative than is generally credited The ingenuity shown is often surprising , perhaps even more remarkable is the parallelism between many of the more specialised of these methods with those in India It is needless to particularise Practically every device from the simplest to the most complex employed on the rivers and lakes of this part of Africa has its counterpart under similar conditions in India M Monod appears not to appreciate this , he envisages the *local* evolution of such a complicated engine as the great balanced dip net (*zemi*) worked from large canoes by the Kotokos, from the triangular hand-net used for dipping out prawns and small fish, a conclusion which does not take account of the presence of the counterparts of this *zemi* on the Ganges Complex devices are seldom evolved separately , through cultural contact they are passed from people to people, and the facts recorded in this volume support the view of the close relationship of certain of the pre-Aryan peoples of India with the Hamites of Arabia and Africa, through whom part of the common material culture has filtered to the Bantus and to a slight extent even to the Sudanese negroes

Such ethnic problems are, however, of academic interest , another aspect of local ethnography has extreme practical importance, and ethnography is inextricably mixed up in the fishery problems of the Cameroons Certain tribes have neither aptitude nor inclination to utilise the fishery

resources of their tribal territories, others are extremely skilful and resourceful in fishing and make the most of their opportunities But prejudice and tribal ties restrict their operations to a definite area, and many stretches of fecund waters are neglected for want of a population interested and adept in fishing Natural indolence is another factor in limiting fishing in many localities to a minimum, there, the people fish only when they feel inclined for a change of occupation No real or professional fishing exists among such people, whose attitude is typified by the remark of a Duala—" This fish work live for kill man, Massa "

The author's conclusions do not encourage the hope of the successful establishment of any extensive fishing enterprise undertaken by Europeans, except perhaps in deep water trawling, about which data are too inadequate to permit of a definite verdict Here, by the way, M Monod has been misinformed in regard to trawling off the Sierra Leone coast (footnote on p 33) in 1912 a steam trawler worked very successfully off this coast, but the enterprise ended in failure through mismanagement and boycott by the market people

The present methods of the indigenous population are usually well adapted to local conditions, and it is rather initiative and application that require to be fostered than the introduction of new appliances Where improvement is most desirable is in the curing of the product As is usual in West Africa, the ordinary cure is a combination of desiccation by artificial and intense heat with concurrent smoking Little was done to investigate the lines on which improvement may be effected, M Monod is a biologist who worked single handed on an inquiry of extremely wide scope, and it is obvious that this industrial phase of the subject should be taken in hand by one who, besides possessing intimate acquaintance with curing methods, has had a scientific education as a bio chemist

JAMES HORNELL

Detection of Poisons

Laboratory Manual for the Detection of Poisons and Powerful Drugs By Prof Dr Wilhelm Autenrieth Authorised translation by Prof William H Warren Sixth American edition from the fifth German edition, completely revised with extensive Additions Pp xxvi + 698 (London J and A Churchill, 1928) 30*s* net

TOXICOLOGY is admittedly one of the most difficult subjects to handle adequately The student is faced with three serious obstacles toxicology requires a considerable period of uninterrupted study, a period which he can seldom afford, the necessary laboratory facilities are not easily found, and finally, after mastering the principles of his art, he is rarely fortunate enough to come across sufficient opportunities of practising them In the East, of course, where from time immemorial the professional poisoner has been rivalled by the gifted amateur, there is no lack of scope for the toxicologist, both in his chemical and also in his forensic capacity

Autenrieth's well known manual, now appearing in English as the sixth American edition, suffers somewhat from the failure of the translator to bring it completely up to date The author gives general methods of handling cases, wisely stressing the impossibility of conducting a toxicological examination on any fixed plan, and rightly indicating that all details connected with the case, such as the medical history—especially a list of all drugs administered—and the results of the post mortem examination, should be given full consideration The method of examination to be adopted depends in many cases upon the toxicologist's experience

The reviewer believes that the book would have been rendered still more useful by including a really comprehensive summary of recent work published in the technical press, with fuller references to that done elsewhere than in Germany The following detailed criticism is offered in support of this belief Under the head of prussic acid poisoning, no mention is made of the delayed form caused by eating cyanogenetic glucosides The symptoms and post mortem appearances are very puzzling until the cause is recognised

Poisoning due to the absorption of nitrobenzene from shoe polishes has been mistaken, clinically, for poisoning by prussic acid, and might be mentioned under the appropriate head Death from drinking formalin may take place in *less* than three hours The reviewer saw one case where a man swallowed one ounce of so-called '40 per cent formalin' and died in about twenty minutes The stomach resembled a tough fibrous mass the size of a cricket ball

It is somewhat surprising that in a book revised by an American so little is mentioned about the toxic effects of methyl alcohol, and that only German references are given Under the head of picric acid, surely some of the information available since the War on this substance and dinitrophenol might have been incorporated

The one-sided nature of the references is illus-

trated by the fact that the Crippen case is not even mentioned under the mydriatic alkaloids group, and the method described in the text of identifying cocaine by the potassium permanganate test is quite useless when really small quantities have to be identified Hankin's modification of the test, published in 1911, is not mentioned, although it is extraordinarily delicate The reviewer has used it for years and cannot speak too highly of it The methods of detecting and estimating arsenic might be condensed with great advantage, and the section on the toxicology of lead would be more valuable if adequate references were given to the enormous literature of the subject Lead tetraethyl is not even mentioned in fact, the section dealing with metallic poisons is very unsatisfactory

The treatment is quite inadequate elsewhere, as illustrated by the section on boric acid as a food preservative, the only reference being to a dissertation published in Munich in 1883 as so much of the valuable work on this subject was done in America, it is quite extraordinary that, in an American translation, no mention is made of Dr Harvey W Wiley In like manner the section on carbon monoxide poisoning might have been written twenty years ago Surely references might have been made to the large amount of recent work

Another example is that of aconitine, the treatment of which is not up to date, the well known test for which, first described by the late Sir Thomas Stevenson, is ascribed to Führer in 1911 ! The comparison of frog heart tracings on a kymograph is not described No mention is made of the identity of yohimbine and quebrachine and the importance of detecting oxydimorphine in certain cases of suspected morphine poisoning is neglected The section on blood stains and the detection of human blood suffers from the same defects, and requires extensive re writing The amazing statement is made that " if the blood stain is perfectly fresh, it may be recognised by observing blood corpuscles with the microscope Human blood may be differentiated from animal blood by comparing blood corpuscles with those of animal blood as to size, only when the corpuscles are still intact " Further on, however, the biological detection of human blood is dealt with, although in a most inadequate manner, no mention being made of Nuttall, or of Dale's anaphylaxis method

The index is poor, and the apparatus described is in most cases archaic The printing is very good, but the binding is not strong enough to withstand the amount of handling such a book would receive as a constant laboratory companion K C B

Our Bookshelf

Allen's Commercial Organic Analysis a Treatise on the Properties, Modes of Analysis, and Proximate Analytical Examination of the Various Organic Chemicals and Products Employed in the Arts, Manufactures, Medicine, etc Vol 6 *Colorimetry, Dyes and Colouring Matters, the Synthetic Dyestuffs, and the Analysis of Colouring Matters* By the Editors and the following Contributors W A Gallup, Hans Edward Fierz David A W Joyce and V E Yarsley Fifth edition, revised and in part rewritten Editors Samuel S Sadtler, Dr Elbert C Lathrop, C Ainsworth Mitchell Pp ix + 658 (London J and A Churchill, 1928) 30*s* net

The seventh volume of this work is considerably different from the corresponding volume in the previous edition Such subjects as tannin natural colouring matters and inks, which were included with synthetic dyestuffs in the old edition have already been dealt with in Vol 5 of the new edition The new book, therefore, is confined practically to an exhaustive study of the preparation, structure, and analysis of synthetic dyestuffs In addition, there is however a small well written section on colorimetry, which might with advantage have been considered in the same volume with other physico chemical determinations

The largest section of the work consists of an article on dyes and colouring matters, in which dyes are classified on chemical lines on the method of Schultz s Farbstofftabellen and of the Colour Index Importance is placed on absorption spectra as the quickest method of identifying a particular compound Synthetic dyestuffs, the next largest section are concerned with the constitution of various dyes by their reduction products The remaining chapters deal briefly with the analysis of colouring matter on the lines of A G Green s ' Analysis of Dyestuffs which the authors use as the main source of reference

The editors have been careful to prevent much overlapping, especially in the closely connected second and third sections, and the work as a whole is well up to the standard of the previous edition There is, however, a slight tendency for it to take the character of a book on special branches of organic chemistry for the specialists, rather than a book of commercial organic analysis of particular value to the analyst The general production of the present volume, both with regard to printing and paper, is excellent, and comparatively few misprints have been noticed J Reilly

Handbuch der biologischen Arbeitsmethoden Herausgegeben von Prof Dr Emil Abderhalden Lieferung 266 Abt 2 *Physikalische Methoden*, Teil 2, Heft 8 *Die Methoden der Erdbebenforschung*. Von Friedrich Errulat. Pp 2151-2262 (Berlin und Wien Urban und Schwarzenberg, 1928) 6 gold marks

The first work in which the modes of investigating a great earthquake were described was Robert Mallet's report in two large volumes on the

Neapolitan earthquake of 1857 (published in 1862) Since then, though methods of studying perceptible earthquakes have been given in various papers, there has been a great want of a more complete treatment of the subject, such as is attempted in this part of Abderhalden's "Handbuch" About two thirds of it is devoted to microseismic methods, to descriptions of the various instruments employed, and to the interpretation of seismograms Two useful diagrams (on pp 2156 57) illustrate the advantage of damping, one showing the similarity of the records of the same earthquake by two damped pendulums (Wiechart and Mainka), the other giving records of the same earthquake by undamped and damped pendulums

The next section, on the investigation of perceptible earthquakes, is slighter than the other The author quotes Sieberg's list of questions, the Sieberg and Mercalli Cancani scales of intensity, and the Sieberg scale of sound intensity The questions seem too numerous for general use, the Sieberg scale of intensity contains too many tests for each degree, leading to the irregular construction of isoseismal lines, while a scale of sound-intensity depends on a very variable instrument—the human ear—and can only be of service when the number of observations is very large In the remaining sections are described very briefly the investigation of submarine earthquakes, of the causes of earthquakes and related subjects (such as periodicity), of the geographical distribution of earthquakes, of microseismic motions, and of the methods of applied seismology If, in parts, the treatment is somewhat scanty, this is a defect that may easily be remedied in a later edition of a very useful work C D

Buried Treasures of Chinese Turkestan an Account of the Activities and Adventures of the second and third German Turfan Expeditions By Prof Albert von Le Coq Translated by Anna Barwell Pp 180 + 52 plates (London George Allen and Unwin, Ltd, 1928) 18s net

PROF A VON LE COQ gives a vivid account of two expeditions to Eastern Turkestan on an archæological mission from the Berlin Ethnological Museum After giving a historical survey, the labours and excitements of the expeditions are narrated, and incidentally there are ethnographical observations and descriptions of archæological remains At one place the expedition arrived too late to save some remarkable Sassanian Hellenistic paintings, and cartloads of Manichæan manuscripts had been thrown into the river by peasants, as paintings of persons are an abomination to Moslems, they are usually destroyed whenever found Another library of priceless manuscripts had been destroyed in the course of time by water Though there were frequent disappointments, various sites offered a rich harvest of frescoes and other objects which can now be seen in Berlin

The narrative is illustrated by beautiful photographs of scenery, people, monasteries, rock temples, and the like, and especially of Hellenistic statuary and wonderful frescoes A reader desiring more detailed information than the somewhat slight amount supplied in this book is referred to the large number of publications which are mentioned in an appendix

The Great Chemists By Dr Eric John Holmyard (The Great Scientists Series) Pp vi + 138 (London Methuen and Co, Ltd, 1928) 3s 6d net

THIS interesting work is essentially a short history of chemistry, written in a very attractive and informative manner Dr Holmyard has shown great skill in weaving the story of the 'Divine Art' about the lives and works of outstanding alchymists, chymists, and chemists, as he follows his pleasant path down the ages from ancient times to the present day Each of the 'great chemists' is chosen as typical of his period, and the names are Jabir, Razi and Ibn Sina, Roger Bacon, Paracelsus, Boyle, Stahl, Priestley, Lavoisier, Dalton, Avogadro, Davy, Liebig, Kekulé, Pasteur, Arrhenius, Mendeléeff, and Ramsay Few readers are likely to cavil at this selection, which manifestly fulfils the author's purpose of imparting a sense of historical continuity to his narrative It is interesting to notice in passing that the list includes five Englishmen and one Scotsman As would be expected, other names are to be found in the text the index refers to more than thirty workers in the cause of chemistry, the most notable absentees which occur to us being the enigmatical Basil Valentine and that potential Lavoisier of the seventeenth century—John Mayow The authoritative chapter on Jabir is to be particularly commended J R

Elements of Optics By Prof Joseph Valasek (General College Physics) Pp xiii + 215 (New York McGraw-Hill Book Co, Inc, London McGraw Hill Publishing Co, Ltd, 1928) 10s net

THIS is an attractive little book on 'light' which would form a good introduction to the subject for those who will not be concerned with technical applications of geometrical optics The sign convention employed by the author would be very confusing in the treatment of any problems but those of thin lenses, and no attempt is made to discuss more complex optical systems on Gaussian lines, except for a short paragraph on thick lenses The discussion of aberrations is limited to brief notes on spherical aberration, chromatic aberration, and astigmatism in their geometrical aspects

Apart from these deficiencies, the chapters on physical optics are well written, and the sections on colour, radiation, double refraction, and the like, bring the older material into co-ordination with modern ideas The mathematics used is confined to elementary algebra and trigonometry

In a book on optics which discusses quanta and spectral series, etc, it is a little surprising that some of the results of the electromagnetic theory should not be used to discuss such topics as reflection Material of this kind should replace the interesting but unnecessary account of 'relativity'

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*]

Spectrographic Chemical Analysis

METHODS devised for the spectrographic analysis of mineral substances were described and results given by the late Prof Sir W N Hartley and myself in a series of papers published in the period 1897–1901 (*Trans Chem Soc*, 71, 583, 1897, and elsewhere) Those methods, however, do not appear to have been utilised by any other workers except one, the late M A de Gramont

In the simplest method then described, a weighed quantity, up to half a gram, of the powdered mineral (the exact weight depends on the type of spectrograph and the type of mineral) was tightly rolled in one half of an ash less filter paper and the roll burnt in an oxy hydrogen or oxy coal gas flame before the slit of a quartz spectrograph, a quartz lens being used to focus the image of the flame on the slit The elements which may be detected by this method when present in small quantities are All the alkalis, copper, silver, magnesium, calcium, strontium, barium, gallium, indium, thallium, lead, chromium, manganese, iron, cobalt, nickel, palladium, ruthenium, rhodium, phosphorus, bismuth, and iridium Other elements which may be detected when larger quantities are present are Gold, beryllium, zinc, cadmium, boron, aluminium, yttrium, tin, arsenic, antimony, sul phur, selenium, tellurium, etc

The list, however, may be extended by placing the poles of an arc lamp horizontally in the flame, a little higher than the point at which the roll of filter paper is being burnt, and adjusted so that the image of the arc is focused on the slit The delicacy of the test is greatly increased on striking the arc, and, in addition, elements such as titanium, molybdenum, and tungsten, etc, give lines instead of only a continuous spectrum Experiments so far made indicate that this is a promising field for in vestigation

The spectrograph used by me since 1913 is a Size C Hilger quartz spectrograph (purchased with a grant from the Royal Society Government Grant Fund) and it gives very satisfactory results The photographic plates generally used have been Ilford panchromatic coated on thin glass Plates 5 in × 4 in, suitably placed in the holder, cover the region required in most work, namely, from the red to beyond λ2800, that is, when no arc is used The filter papers recom mended are Munktell's Swedish, No 00, diameter 12 5 cm This spectrograph and method have been used, qualitatively and quantitatively, in the analysis of flue dusts containing gallium and in extracting gallium from flue dust It is seldom necessary to take more than 0 1 gm, and smaller quantities usually suffice

The method has also been applied to the analysis of vegetable and animal substances In examining vegetable material, the twig, straw, leaf, or other part is held by forceps and burnt in the flame without introducing any impurity, even in the form of ashless filter paper By taking weighed quantities, usually 0 1-0 25 gm, the quantities of the mineral constituents can be compared, as, for example, in plants grown in different soils, etc, or in plants such as wheat at different stages of growth, or before and after watering with mineral salts Many interesting results have been obtained in this way

As an example it has been established that rubidium is very widely distributed in soils and in the plants grown on them Further, the growing point of cereals is relatively richer in rubidium, as compared with potassium, than the other parts of the plant It is possible that rubidium is more freely absorbed than potassium, as potassium seems to be more freely absorbed than sodium, but it seems more probable that potassium and rubidium pass up in the sap with equal freedom and that the potassium diffuses or transfuses more readily away from the growing point

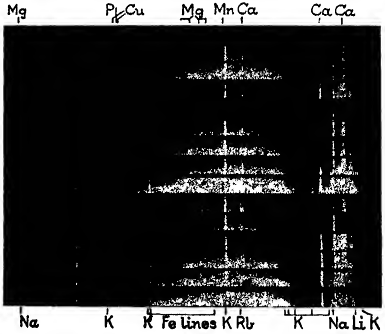

FIG 1 —Stem of wheat grown in soil to which lithium potassium and rubidium salts were added Top four spectra leaves next four sheaths next three grain stem and chaff of ear last four straw sections The first of each set of four was the oldest and the others follow in order of age Cut when the ear was nearly half filled

Animal matter, or soft vegetable substances, may be examined by rolling 0 5 gm in ashless filter paper, but it is better in most cases to dry them in a steam oven and to take 0 05 gm of the powdered dry residue in a smaller piece of filter paper The various organs of an animal may easily be compared for mineral constituents in this way

In some experiments a wheat straw with ear has been divided into eighteen parts grain, leaves, sheaths, and sections of straw, and the eighteen spectra photographed on one plate so that comparison is easy and the record is permanent, the burning occupies twenty to twenty five minutes

During the recent vacation, experiments were made with measured quantities of blood, and it was found that the best results for comparison were obtained by taking 0 1 c c on ashless filter paper Samples of

normal blood and two samples from anæmic patients, kindly supplied by Dr G P Claridge of Norwich, were analysed and distinct differences were noted in the iron, calcium, magnesium, and potassium content Further, the rubidium line λ4202 was present in the spectrum of the normal blood, rubidium, in fact, is present in most parts of the body, and it is present in both human milk and cow's milk

It will be seen that there should be many applications for methods of spectrographic analysis on the lines described above The spectra contain few lines as compared with arc or spark spectra, and the lines are easily identified in practice The methods are worthy of more attention than they have received and they should be especially useful, and possibly prove indispensable, to those interested in the detection and distribution of the metals essential to life, and even of phosphorus, in the parts of plants and animals

Evolution through Adaptation

DR BATHER's interesting survey of "Evolution through Adaptation" in NATURE of Mar 30 prompts a few supplementary suggestions There is a tendency in writing upon this subject to think of 'a variation' appearing in the soma under some stimulus which, if maintained for a sufficient number of generations, may produce in the germ a mutation in harmony with the variation in the soma The concept of a mutation of the germ, arising in such a way as to harmonise with an alteration in the soma that has already appeared, is a concept which strains probabilities in many, though not necessarily in all, types of cases Dr Bather's illustration of an animal with defective pigment and sight skulking in dark corners, where alone it is likely to escape its enemies, is used by him to suggest selection of environment by organism, but it is also a reminder to come back to thought of the organism as a whole

Experiment and observation have shown that considerable alterations in the balance of growth can be produced in a population through alteration in environmental influences Such influences operate in Nature generally, we have clear evidences of secular variations of climate through the geological periods, and we know that, in spreading, a form of life encounters modified conditions as its range extends itself

Observation and experiment further show that for various stocks there are 'fringing conditions' under which the individual can indeed live, and even, it may be, grow, but the race cannot reproduce itself, or can do so only very exceptionally The sensitiveness of the reproductive process is a noteworthy fact

If now we set these two points side by side, we may picture a 'marginal case' Let us suppose that the changed conditions of the environment have induced changes of growth, but that the germs remain as before These germs are presumably like all living things in that no two are alike Some variations in them may be towards greater, and some towards lesser, viability in the altered environment It will be from the former that the survivors will be bred We thus think of a process of selection operating on the germs, and operating so as to eliminate, very probably, quite a large proportion of them It is a selection not of a germ that has mutated so as to produce a change in harmony with some change that has appeared in the soma, but a selection of a germ viable in an altered environment The plea here is one which to some extent supplements Dr Bather's suggestions, or, for that matter, Prof Lloyd Morgan's concept of organic selection, for it demands less in the matter of variation of the germ It looks upon variation of the environment of a stock, whether because that stock spreads in space, or lasts through phases of climatic change, as in some sort the initial factor, and it suggests that the extra sensitiveness of the reproductive process, as compared with the other vital processes, is one of the main determinants of the viability of a stock in a fringing zone of distribution It looks upon the germ as basic capital undergoing slow modification, less through the addition of particular mutations corresponding to changes already in the soma than through the selection under marginal conditions of viable variants

These suggestions are in no way in opposition to Dr Bather's, nor does the point of view here developed conflict with that of the advocates of organic selection It merely attempts to supplement them by burrowing under the problem of the inheritance or non inheritance of acquired characters It leaves abundant room for the idea of evolution by germ mutations and so on, and it suggests that growth changes may be essentially physiological responses, some of which may increase, others decrease, viability It leads on to the suggestion that, as cumulative growth changes occur as responses to cumulative environmental change, and are themselves followed, at a long interval, by attunements of the germ which are attunements to environmental changes, the germ in the course of its evolution becomes more and more highly specialised the more and the more recent and the more rapid have been its attunements Thus, if a new series of environmental changes should afterwards supervene, such a highly specialised organism would be less likely to be able to respond than would a less specialised form, a form which had had a longish record of relative evolutionary passivity

H J FLEURE

Aberystwyth

PROF FLEURE is careful to explain that his remarks are not in criticism of anything said by me; yet they seem intended to evade the difficulty that I have found in certain beliefs for which there does appear to be some evidence—the difficulty, namely, of understanding why and how a germinal mutant does appear sometimes to accord with a previous modification of the soma Prof Fleure says this "is a concept which

strains probabilities " Many biologists of no less distinction have regarded the concept as more than probable It is by no means clear that such examples of the transmission of impressed characters as Prof Przibram brought to our notice the other day fall within this concept they seem to be instances of reversible modification Among facts that do support the concept are those genetic analyses of populations adapted to a special environment which have shown that the adaptive characters of some individuals are due to somatic modifications, while those of others are inherent in the germ Cuénot (" L'Adaptation,' 1925) cites in illustration *Centaurea jacea*, forma *humilis*, in the Swedish salt marshes, Gregor and Sansome (*Jour Genetics*, 18, p 349 1927) have traced a similar mixture of mutants and modifications in wild grasses The bearing of these observations on adaptive evolution was discussed in my presidential address to the Geological Society (1928)

In the explanation of adaptation now put forward by Prof Fleure it is not easy to detect anything more than the old Darwinian idea of indefinite continuous variation and selection of such forms as can live in the changed environment Let the environment change ever so greatly, some of the germs will be able to persist and so the line alters from species to species, and from genus to genus (or grade to grade), without any actual change in the germ The original germ has in it the potentiality of all this development If this is what Prof Fleure means, surely he is basing his conclusions on a view long since discarded It is generally agreed now that there are limits to fluctuation, just as there are to individual modification

A palæontologist can produce no evidence for or against such a view he is bound to consider the evidence of workers in other fields, and this, at present, indicates that change (mutation) does affect the germ and that successive mutants, by however little they are distinguished, are actually discontinuous Evolution is by quanta Accepting this, the palæontologist applies it to the phenomena with which he is familiar, and his analysis, if carried far enough, will lead him to those questions to which my Royal Institution discourse attempted to suggest an answer When Prof Fleure writes of attunements of the germ to environmental changes, he merely states in metaphorical language a fact which—if it be a fact—demands an intelligible mechanism

F A BATHER

Spiral Markings on Carborundum Crystals

THE phenomenon described by Prof A W C Menzies and Mr C A Sloat in NATURE for Mar 9, p 348, can, I think, be explained from some results I obtained in 1925 in connexion with the banded crystallisation of sulphur films

The inside of a test tube was covered with a film of molten sulphur by vigorously boiling some of the substance inside The test tube was then lightly plugged with cottonwool and allowed to stand upright After the draining film had cooled almost to room temperature in a few minutes, centres of crystallisation appeared at various points, and rings could be seen growing in succession outwards from the central points The accompanying enlarged photograph (Fig 1) of the test tube shows the result

I found that good rings were obtained in hard glass test tubes, or soft glass which had been cleaned with concentrated sulphuric acid, but that only poorly developed rings could be got in ordinary soft glass test tubes, particularly if alkali was present

I also found that by counting the number of rings from a centre and measuring the distance also from the same centre occupied by these rings and then plotting the logarithm of the number against the logarithm of the distance, an excellent straight line was obtained in every case In one experiment I counted 89 rings or parts of rings in one direction from the centre

The general equation for these straight lines is

$$\log N = a \log r + \log K$$

where N = number of bands, r = distance $\log K$ is the intercept on the axis of $\log N$, and a is the slope of the line to the axis of $\log r$ This gives

$$N = Kr^a$$

as the law of formation of the rings

The explanation of the formation of the rings I had arrived at and considered satisfactory was that the first small crystal formation at the centre caused evolution of latent heat which consequently rendered

FIG 1

the surrounding sulphur more mobile and diminished its surface tension This mobile ring of liquid sulphur was then drawn outwards away from the centre to form a circular ridge which however very quickly crystallised with liberation of more latent heat and formation of another mobile ring and so on That the sulphur is drawn away from the centre by surface tension is clear from the photograph, because the centre is a depression, not an elevation Also the flow can actually be witnessed by means of a lens during crystallisation

It seems that the sulphur has to be in the labile state for these rings to form If it is in the metastable state, then only large crystals grow slowly in the film Some of these can be seen as irregular patches in the photograph

I have measured the rings in the photomicrograph reproduced in Messrs Menzies and Sloat s communication (*loc cit*), both in the direction west of the centre and in that N N W of the centre, and find that the logarithm of number against logarithm of distance give beautifully straight lines In the case of the latter direction (N N W) a is very nearly unity and K 0 417 mm

I would therefore suggest that the spiral formation observed by them has been produced in a similar manner to the sulphur rings described above Further-

more, there appears to be no particular significance in the spiral nature of the markings. It may be noted that Hedges and Henley (*J.C.S.*, October, p. 2725, 1928), in connexion with their work on Liesegang rings, describe spiral formations as anomalies due to accidental external conditions.

A Principle of Duality and the Causal Law.

The possibility of a causal space-time description of experience has recently been often denied, and emphasis has been laid upon the purely statistical validity of quantum theoretical relations. This denial of a possible causal space-time description has aroused suspicions and diffidence in regard to the newer physics. The purpose of this note is to show that there is no need for the above denial and that we have not only one possibility of a causal space-time description of experience, but actually two of them. This superabundance of possibilities of description is the very reason, as we shall see presently, why some relations can have only statistical validity.

It is well known that light can be described either as a propagation of spherical electromagnetic waves or as the linear translation of corpuscles of energy and momentum (light quanta); that electrons appear sometimes as point charges and at other times as matter waves; that the atom itself can be pictured, in the case of hydrogen, either as a planetary system of attracting particles (Bohr's theory) or as a system of stationary waves (De Broglie, Schrödinger). Furthermore, it is easy to show, as will be done more fully elsewhere, that the process of emission of light can be described either as the sudden spontaneous ejection of a light corpuscle a finite time (*Verweilzeit*) after the excitation, or as the continuous radiation of a set of spherical damped waves beginning at the very moment of excitation, the inverse of the damping coefficient of which is equal to the extinction time (*Abklingzeit*); that absorption can be interpreted either as the sudden jump of the molecule from one stationary state to another owing to the impact of a light quantum, or as a classical damped resonance of the molecule with the on-coming wave; that optical resonance appears either as sudden absorption with subsequent sudden emission after a time determined by a coefficient of 'spontaneous' transition or as continuous scattering (dispersion), in which the secondary radiation is coherent with the primary (Wood's experiment showing regular reflection of mercury vapour for λ2537). Moreover, Schrödinger (*Ann. d. Phys.*, 82, 257; 1927) has shown that the Compton effect can be described from the point of view of waves as well as of corpuscles, and Heisenberg (*Zs. f. Physik*, 40, 501; 1926) has made clear that both points of view are equivalent in explaining the phenomena of fluctuation. Photo-effect and electron collisions can also be described equally well from either viewpoint.

All of the examples given above show clearly that there are many physical phenomena which can be described in two ways using either one of two essentially different systems of concepts and definitions. The two systems by no means complement each other; *they exclude each other*. Every attempt to superpose the two descriptions in order to reach a unified one leads necessarily to breaks in the laws of conservation of energy and momentum, as has been shown by the many unsuccessful attempts to describe light as energy-momentum centres moving along the Poynting's vector of a wave field (virtual or probability waves).

Now it is easily seen that a space-time description is readily possible using either one of the two systems of concepts and definitions (waves or corpuscles) so long as we keep inside of one of them, and that in this case there is possibility of predicting the future of a physical aggregate which is limited only in the case of a corpuscular description by the principle of indetermination of Heisenberg and Bohr. The classical claim of causality can be maintained in each system. In the corpuscular system we must realise that it is impossible to determine all of the initial conditions of a physical aggregate beyond a certain degree of accuracy. This limitation is unnecessary in a wave description, since the principle of indetermination is superfluous in this case. The classical claim of causality is met here without restriction.

The causal space-time description of the whole of physics remains for the present only a programme, in spite of the dual possibility, owing to the fact that certain phenomena, like interference, can be described satisfactorily as yet from only one point of view. In an all-embracing quantum theory, therefore, it is necessary at present to make use of both systems of concepts at the same time and to jump from one to the other according to the exigencies of the case. At the instant of the jump, every possibility of a space-time description disappears and the magnitudes calculated in one system can have only statistical validity in the other. This is the deeper reason for the purely statistical validity of some relations of quantum mechanics.

The breaks in the space-time description of experience are only a sign of the times, and we may hope in the near future to be enabled to make a causal description of physics in space and time, using a single set of concepts and definitions.

Diffraction of X-rays by Two-dimensional Crystal Lattice.

In usual experiments with diffraction of X-rays by crystals, an effect of space lattice is always observed owing to the penetration of the rays into the depth of the crystal. The thin layers, however, in which one

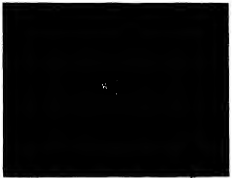

Fig. 1.

could expect the appearance of diffraction by the two-dimensional lattice, scatter the rays too little, and therefore the experiment becomes impossible. The matter is different in a crystal cleft into very thin layers in such a manner that the orientation of separate layers is not destroyed. This may be well

done in mica simply by heating it to red heat and then cooling; but not so well by carefully crushing plates of other crystals. When a thin beam of X rays passes through such a plate, the effect of two dimensional lattices will be added, whereas the space effect will be destroyed by the incoherence of waves produced by scattering from incorrectly spaced layers

On the photograph (Fig 1) obtained by this method with Cu radiation from mica, is seen a system of spectra corresponding to a series of two dimensional lattices making different angles with each other

From the measurement of these spectra the distribution of molecules in the layers of mica may be determined All the spectra obtained may be explained by assuming that the molecules are distributed in the summits of equilateral triangles the sides of which are equal to 5 2 A

The phenomenon is quite analogous to the diffraction of cathode rays from mica obtained by Kikuchi (*Japanese Journal of Physics*, vol v No 2)

Somewhat more diffused photographs by the same method are obtained from gypsum and Iceland spar

A photograph taken of a crystal before cleavage gives the usual Laue figure

Owing to the facility of interpretation of the spectra of a two dimensional lattice, this method may be of service in the study of crystal structure

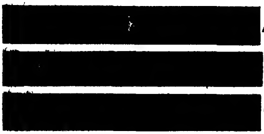
High Frequency Discharge in Gases

For some time past we have been studying the problem of high frequency discharge through air and other gases In the course of our investigation we found that whether the electrodes are of external metal sleeves or are of internally sealed aluminium wires, steady striations always appear in the tube under suitable experimental conditions Recently



A
B
C

Fig 1

Heidemann (*Ann d Physik*, **85**, Nr 6, 1928) and Dr S P McCallum and Mr W T Perry (Nature, Jan 12, 1929) have observed striated discharges in hydrogen and argon with external electrodes The general nature of the striated discharges appears to be the same in all gases Over and above what they have noted we have been able to observe certain new characteristic features of the discharges

(1) There is a striking difference in the nature of striations with internal and external electrodes Whereas with external electrodes the striations are generally of the nature of 'double layers' (Heidemann and McCallum and Perry), with the internal electrodes they have always a comb like appearance excepting at very low pressures

(2) As the pressure is lowered the thickness of the striae increases At a still lower pressure the glow extends *beyond* the electrodes and striations can be observed in this region also (Fig 1A)

(3) The same glow discharge can be obtained with only one external electrode In this case the discharge is always of the form of two convergent beams with their apexes away from the electrode (Fig 1B) The beams after converging, however, again begin to diverge from the apexes It will be noticed that there are two very prominent dark spaces in the region beyond the electrode Beginning from this the discharge generally passes into a uniform glow But, with suitable pressure and power regulation the glow can be made to break up into striations (Fig 1C) It will be seen from the photographs that these striations become more prominent as the distance from the electrode increases

Magnetic Behaviour of Organic Crystals

The interesting observations of Sir William Bragg on the deportment of crystals of naphthalene in a magnetic field (Nature, Supplement, May 7, 1927) have been followed up quantitatively in this laboratory, and some very significant results have been obtained. It is found that the diamagnetic anisotropy of naphthalene is extremely pronounced, the susceptibilities along the three magnetic axes of the crystal being approximately in the ratios 16 7 4 That such a high degree of anisotropy is to be expected in aromatic compounds is indicated by the data for magnetic birefringence in liquids, as had indeed been shown earlier (C V Raman and K S Krishnan, *Proc Roy Soc*, A, vol 113, p 511, 1927) Mr S Bhagavantam, who made the measurements, finds that the axes of maximum diamagnetic susceptibility and of minimum optical dielectric constant in naphthalene crystals are approximately coincident This observation explains why organic liquids derived from naphthalene, and indeed also aromatic liquids generally, exhibit a strong *positive* magnetic birefringence We may further expect to find that in aromatic compounds generally, the magnetic and optical characters are linked together more or less in the same way as in naphthalene crystals

The magnetic behaviour of organic crystals of the aliphatic group of compounds is different Not only is the anisotropy, in general, less pronounced, but also the relation between the magnetic and optical characters is more varied In some crystals, for example, iodoform, Mr Bhagavantam finds the axes of maximum magnetic susceptibility and optical dielectric constant are parallel, while in others, for example, urea, they are crossed These facts have a bearing on the explanation of the fact that liquids of the aliphatic class exhibit a magnetic birefringence which is usually much feebler than in aromatic liquids, and further that in some of them the magnetic birefringence is positive and in others negative An extended series of measurements of magnetic birefringence in liquids of the aliphatic class is now being made by Mr Ramanadham here, and is serving to elucidate the relationships between the optical and magnetic characters of organic compounds and their dependence on chemical constitution

Since the position of the magnetic axes of a crystal depends on the orientation of the molecules in the unit cell of the lattice, it is clear that the studies of magnetic behaviour of organic compounds will form a powerful auxiliary to X rays in the analysis of their crystal structure

Effect of X-rays on Seeds

THE effect of X rays on growth and development is a subject which has always caused considerable interest. It can be studied most easily in plants where cell division takes place so rapidly that daily growth can be observed

We irradiated various kinds of seeds, chiefly broad beans, barley, and mustard, the effects on these forms being dissimilar although the conditions and the dosage were exactly alike It would appear, therefore, that a specific dose is required We used approximately three times the dose of X rays which would cause the human skin to redden, at 120 kilovolts In every case the seeds were covered with black paper to protect them as much as possible from the light and heat from the tube

The broad beans gave the most rapid and striking results Seeds which had been planted for different lengths of time, varying from one week to a few hours, and also dry seeds, were employed, an equal number of seeds in each case being used as controls Stunting followed irradiation in all those which had been growing for more than 24 hours The changes were not observable for some days (two or three) and were first seen in the oldest seeds, but beans which had been growing for 48 to 72 hours appeared to be most sensitive In addition to being stunted the roots appeared to become slightly bulbous at the tip In most cases the shoots appeared later than in the controls, but sometimes failed altogether Side roots never appeared in the stunted X rayed specimens

In mustard seedlings the only detrimental result was the failure of the side roots to develop, and that only in the seeds which had been growing for more than 72 hours before they were irradiated An extremely small dose (about $\frac{1}{10}$ of above) appeared to cause more rapid growth

Little alteration was found in the roots of the barley, as in this plant the shoots were most radio sensitive and showed very much less growth than the controls

Local Extinction of a Recently Abundant Lamellibranch

THE Lamellibranch *Spisula subtruncata* (Da Costa) is reported in various old records as occurring abundantly in parts of the Clyde Sea Area For example, in "The Mollusca of the Firth of Clyde," 1878, p 33, A Brown writes "Exceedingly abundant a little above low water in Ettrick and St Ninian's Bays, Bute, and in Fintry Bay, Cumbrae It is common also all along the Ayrshire coast, and in most sandy bays throughout the district In Cumbrae they are known as 'Aikens,' and are used both for food and bait" Further confirmation is found in the *Medusa* records and in the fauna and flora published for the British Association in 1901—records of almost thirty years age and older

By contrast with these records of abundance one of us (R E) cannot recall ever having seen a living *S subtruncata* in the course of twenty years In recent years we have made a very careful search for this species in Cumbrae, Bute, and the Ayrshire coast, etc, without finding a single living specimen, although the shells occur in millions in Kames Bay, St Ninian's Bay, and Hunterston sands

Further, inquiries amongst fishermen reveal the facts that old men (70 80 years) immediately recognise *S subtruncata* as 'Aikens,' and assert that they knew them and used them in youth and middle life, but "have not seen a single full one for thirty years or more" Similar evidence is got from younger men, until we reach men of 45 or so, who say they have never seen or used them although their fathers did

In short, there is good evidence that *S subtruncata* died out in this district about thirty five to forty years ago Type samples of the dead shells have been sent to the Royal Scottish and British Museums and the Fisheries Laboratory at Lowestoft

Successive α-Transformations

IT is well known that, in such parts of the radioactive transformation series as are not disturbed by β emissions, the successive α particles are shot out with ever increasing energy The paradox that, although the probability of emission increases so enormously with the energy, it is the slowest particles that first come out, has once again come to the fore now that wave mechanics has led to a theoretical connexion between energy and decay period It seems worth while to point out that this difficulty can be very simply explained if we assume that all the α particles in question are originally in the same quantum state For if N interacting particles have the total energy NE they will not each fly away with the energy E, it will depend on the nature of the forces acting between them whether the first ones take more than their share or less

A simple example is provided by the helium atom, the removal of one electron involves binding the other closer, and the remaining electron has less energy than it had before the removal If a helium atom is placed in an electrical field it has, according to wave mechanics, an intrinsic probability that it will become ionised (Oppenheimer, *Phys Rev*, **31**, p 66, 1928), and owing to the above energy relation the second ionisation will take place more slowly than the first In the helium atom we have the case that the particles in question, at the distances in question, repel each other, in a radioactive nucleus we have the opposite case For by hypothesis the particles here are so close to one another that their attractions outweigh their repulsions, it follows at once that the first particle is the most difficult to remove

Astrophysical Estimate of Ionisation Potential of Vanadium

IN a previous letter (NATURE, June 9, 1928) I outlined the method by which estimates of ionisation potentials might be derived from the spectra of Cepheid variables Many of the lines emitted by ionised atoms are intensified at or near maximum luminosity phase and diminish in intensity as the star passes through the phase of minimum light Many arc lines, on the other hand, show the reverse tendency By comparing the behaviour of certain ionised lines with spark lines due to titanium, scandium, strontium, and barium, the ionisation potentials of which are known, it has been possible to estimate this constant for iron, yttrium, and lanthanum (loc cit), and quite recently for vanadium From the periodic changes in intensity of the ionised line λ4205 07 I have obtained for the *ionisation potential of vanadium* 6 74 *volts*, the final figure being extremely uncertain.

In a recent letter from Dr W F Meggers, Bureau of

Standards, Washington, I am reminded that Prof H N Russell (*Ap J*, 66, 1927) has obtained the principal ionisation potential of vanadium from spectral séries relations to be 6 76 volts I am un aware of any laboratory determination of this quantity, but the close agreement between the spectroscopic and the present astrophysical determination is very satisfactory

As before, I am under obligations to the Director of the Dominion Observatory, Ottawa, for the loan of the spectrograms from which my microphotometer graphs have been made A VIBERT DOUGLAS

Raman Effect and Fluorescence

SIMPLE probability considerations reveal an interest ing relation between fluorescence and the modified scattering of light If N_r, N_s, etc , be the number of systems in the energy levels of energy values E_r, E_s, etc , the induced probability of transition $E_s \longrightarrow E_r$ may be denoted by W_{sr} If $E_s > E_r$ this causes the emission of a quantum $h\nu_{sr} = E_s \; E_r$, which fuses into an external quantum $h\nu$, so as to form a new quantum $h(\nu + \nu_{sr})$, giving rise to negative or anti Stokes lines The total energy so radiated is $N_s \; W_{sr} \; h(\nu + \nu_{sr})$

Similarly the transition $E_r \longrightarrow E_s$ gives rise to the positive lines of frequency $\nu - \nu_{sr}$, and its total energy is $N_r \; W_{rs} \; h(\nu \; \nu_{sr})$ As a result, the s^{th} level acquires a surplus number $(N_r - N_s)W_{rs}$ systems $(W_{rs} = W_{sr})$ We postulate that thermal agitation restores the normal distribution so that this surplus number reverts to the r^{th} level, emitting total energy $(N_r \; N_s)W_{rs} \; h\nu_{rs}$ of frequency ν_{rs} We identify this radiation with fluorescence Of course it is in the infra red, when the modified lines are visible When ν_{rs} nearly equals ν, it will be shown with the help of Born s formulæ, in a paper appearing elsewhere, that the factor W_{rs}, since it involves a term $k/(\nu^2 \; \nu_{rs}^2)$, becomes very large so that the intensity of a fluores cent line (now visible) is much greater than a modified visible line, as is actually the case

Indication of Hydroxyl in a Water Vapour Discharge Tube

THE presence of OH in the gas coming from a water vapour discharge tube has been demonstrated by photographing the exit tube with a quartz spectro graph the well known band at 3060 A was obtained Addition of a small quantity of oxygen to the water vapour has the effect of increasing the intensity of the bands, a larger amount of oxygen causes the appearance of the green oxygen afterglow This glow is continuous in the visible and is accompanied by the OH bands in the ultra violet The active gas appears to possess both reducing and oxidising proper ties This is illustrated by the simultaneous reduction of copper sulphate to copper oxide and metallic copper and the oxidation of metallic silver In both instances heat effects have been observed The glow appears to be unaffected by the copper sulphate, but is removed by the silver An extensive study of the conditions determining the production of OH, its separation from any other active constituents which may be present, and its chemical properties are now under way in this laboratory

The Green Flash

HERE at 700 feet above the sea the green flash at sunset may be seen whenever the horizon is clear of clouds At times the air is so clear that the moun tains of St Vincent, 110 miles to the west, can be clearly seen at about the time of sunset On such evenings Venus may be followed right down to the sea horizon when as now, it is near its maximum brightness

A few nights ago I watched the planet setting through a pair of field binoculars About five minutes or so before it set there was a great deal of change of colour from red to peacock green, but it was quite evident that the red colour was on the whole below and the green above showing that the image of Venus was being drawn out into a short spectrum When the planet was very nearly on the horizon the colour changed several times from red to green and vice versa, but just as it disappeared the image was of a distinct peacock green

This observation shows that the explanation of the green ray is physical (refraction) as now generally admitted, and not physiological for the light from Venus was not nearly intense enough to produce an after image C J P CAVE

African Pluvial Periods

THE interesting remarks in the News and Views columns of NATURE for Mar 16 with reference to Bushveld man and Mr Leakey's discoveries in Kenya, direct attention once again to the Pluvial periods of Eastern Central Africa I should like to be per mitted to point out that while the theory which finds reason for a genetic connexion between these pluvia tions' and glacial episodes of higher latitudes is sound enough, and although there is evidence to show that in all probability some such connexion existed, the correlation of Kenya pluvials with definite periods of the Pleistocene as recently set forth, is purely hypo thetical There is room for discussion concerning them, and according to my showing which may of course be wrong, the Kenya archæological expedi tion s third pluvial is so to say, an epi pluvial, and is (if anything) Buhl and not Wurm in date and so *mutatis mutandis* with the others The Expedition s ground in the Rift Valley is likely to be full of pit falls, and in my opinion a great deal of work must be done there before one can say with confidence which of certain deposits are pluvial and which are not E J WAYLAND

Beryllium and Helium

IN a letter on the 'Transmutation of the Lighter Elements in Stars (NATURE April 13, p 567), R d E Atkinson and F G Houtermans remark that "the isotope Be^8 is probably unstable (it does not occur on the earth) and will then almost certainly break up into two helium nuclei "

I am reminded of an observation made many years ago It was found (*Proc Roy Soc*, A, vol 80, p 587, 1908) that specimens of the mineral beryl always contained helium without appreciable quantities of radioactive matter to explain its presence

Can it be that this helium has originated from the isotope Be^8? If so, it would indicate that the isotope in question, even if it does not exist now, *has* existed within geological times, and subsequent to the forma tion of the mineral RAYLEIGH

Terling Place, Chelmsford,

Geological Aspects of the Channel Tunnel Scheme

By John Pringle

THE numerous advantages that will result from the making of a tunnel between England and France have long been recognised, but it may not be generally known that in support of such a scheme legislation dealing with the preliminary procedure passed both the French and British Parliaments so long ago as 1875 Less than five years later a start was actually made and headings were commenced on both sides of the Channel, but the failure of the French Channel Company, followed by an order issued by the British Government to close down the work of the British engineers, brought the project to a standstill Now that the scheme has been revived it is hoped that the undertaking will be pushed through to a successful issue Geologists agree that the excavation of the tunnel is practicable, and no obstacles which will defeat the ingenuity of engineers are likely to arise in the course of its construction

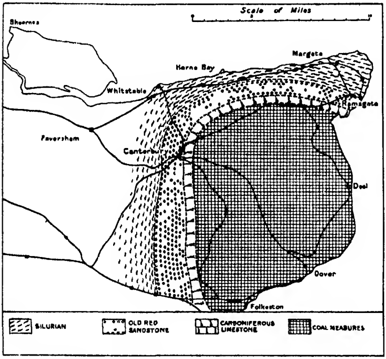

Fig 1 —Sketch map of the Palæozoic strata proved at depths varying from 900 ft to 1400 ft below Ordnance Datum in East Kent

During the years that have elapsed since the heading was stopped at Dover, much has been learned concerning the deep seated geology of East Kent and of the opposite shore of France, and some of the results obtained may not be without interest at the present juncture

It seems scarcely necessary here to relate the views held by early geological observers concerning the physical identity of the coalfields of Somerset with those of the north of France, and the continuity of the higher formations in both countries, nor does it seem needful to do more than merely mention that the theories advanced in 1855 by Godwin Austen, in a remarkable paper "On the Possible Extension of the Coal Measures beneath the South Eastern part of England," gave rise to considerable interest in the problems connected with deep seated geological structures It is sufficient to say that most geologists were so certain of the occurrence of Coal Measures under Kent that Prestwich in 1873 maintained that these old rocks would be found sufficiently near the surface at Dover to allow submarine tunnelling Picturesque accounts of the excavations of a tunnel by working the coal made their way into the columns of the newspapers When the boring made alongside the Channel Tunnel shaft at Shakespeare Cliff proved the presence of Upper Carboniferous Rocks with seams of coal, a great impetus was given to further exploration by the boring tool, and since 1886 more than forty borings and shafts have been carried down to the Palæozoic rocks in East Kent

The information obtained by many of the companies carrying out these explorations was, however, jealously guarded for commercial reasons, and had it not been necessary to seek the advice of geologists, perhaps few details of the borings would have become public knowledge Fortunately, the advice of the officials of the Geological Survey was sought, and they were permitted to examine the cores of nearly all the boreholes The excellent use made of these opportunities resulted, when publication was allowed, in contributions to geological science of the highest value These borings have demonstrated that Kent, instead of being an area of simple geological structure, as was thought, is one of considerable complexity, and more geological formations have been proved underground in that county than in any other in England

As an outcome of the work of the Geological Survey, it is now possible to map the Palæozoic platform, and to show the area occupied by the Silurian, Old Red Sandstone, and Carboniferous rocks (Fig 1) Further, a plan can also be made of the disposition of the Jurassic rocks on the Palæozoic floor and the general arrangement they would present, if all the strata down to the base of the Wealden were removed (Fig 2) Fig 2 is based on that published by the Geological Survey, but certain modifications of the outcrops of the

formations have been made by me to incorporate later information All of these formations are buried beneath a great thickness of Cretaceous and Tertiary deposits, some of which are depicted on Fig 3, and the great anticline of the Weald has been shown to be a purely superficial structure superimposed on an underlying syncline

In Northern France borings have also been made since the heading was driven at Sangatte near Blanc Nez Here the Cretaceous rocks are nearly identical with those of Kent, but the Wealden anticline, which is prolonged into France, has been denuded down nearly to the oldest Jurassic strata These occupy the low lying tract known as the Boulonnais, and they are surrounded by chalk hills In places, inside the ring of chalk, Palæozoic rocks are exposed at the surface, and this fact gave rise to the idea that a Channel tunnel might be excavated throughout in the older strata At Dover, however, the discovery of Coal Measures at the depth of 1158 ft below Ordnance Datum showed such a scheme to be impracticable, quite apart from other difficulties arising from the heavily watered Hastings Sands and Inferior Oolite

The most important formations to be considered in the making of this tunnel are the Gault and the Lower Chalk The lithological similarity of these rock groups as exposed in the cliffs of Kent and in the bold headland of Blanc Nez is so close as to make it certain that no important change in mineral characters takes place in the beds immediately underlying the floor of the Channel For example, the thickness of the Lower Chalk remains practically constant in Kent it is 193 ft, at Blanc Nez, 189 ft The work on the Channel Tunnel can thus be carried out with the advantage that identical strata are to be penetrated at each end

The chief and, one might say, the only engineering difficulty likely to be encountered in constructing a tunnel in the Chalk would arise from the presence of water, and regarding the question of the amount and distribution of water in this formation many useful data have been obtained from the borings, shafts, and other works made in Kent and in northern France during the past forty years The knowledge may be summarised as follows in the Upper Chalk there is a great amount of water, in the Middle Chalk and perhaps in the higher part of the Lower Chalk there is a smaller quantity, but in the remaining portion of this lowest subdivision, the Grey Chalk and Chalk Marl of older writers, except in fissures, little or no water is found, in consequence of the increased amount of argillaceous sediment in this part of the series Thus, the lower part of the Lower Chalk, which has generally been considered the most advantageous position in which to drive the tunnel, is favoured by all recent experience as the driest and most homogeneous part of the Chalk for this purpose

At the same time, the relative dryness of the Lower Chalk does not preclude the possibility of meeting water in some quantity in that subdivision The Chalk, like most other formations, has been subjected to pressure and folding, giving rise to faults and fissures These have a west north westerly trend in Kent, and a similar direction has been noted in France They allow the passage of a considerable volume of water, even in the Lower Chalk Thus, for example, a strong spring is given off from a fissure in the Lower Chalk at Lydden Spout, west of Shakespeare Cliff

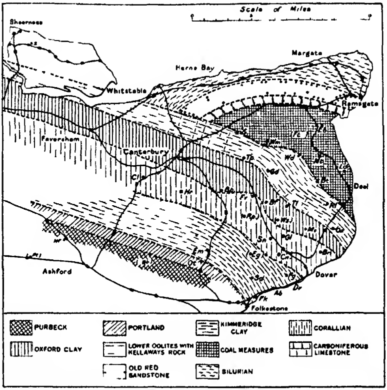

Fig 2 —Sketch map showing the disposition of the Jurassic strata on the Palæozoic floor in East Kent Boring sites shown thus Dv, etc

Obviously, therefore, much will depend on the relation of the tunnel to the trend of the fissures Where the headings run parallel with the fissures little or no water need be expected This was clearly demonstrated by the experience gained in driving the headings at Dover and at Sangatte on the French side of the Channel At Dover a heading 7 ft in diameter was driven for a distance of more than 2000 yards, in a direction approxi-

mately parallel to the lines of faults and fissures A small amount of sea water made its way into the workings, but a hand pump was found sufficient for dealing with the flow, the water caused no inconvenience, and was easily kept out by a ring of tubing After an interval of nearly thirty years the heading was reported to be dry in 1912 On the French side, however, the engineers experienced much trouble in dealing with the water coming from a fault in the lower part of the shaft, and in a length of the heading driven nearly at right angles to the fissures a fair amount of water was also tapped

The excavation of the lower part of the Lower Chalk is therefore not likely to be entirely free from water troubles The difficulties, in fact, may be increased if the original plans for the drainage of the tunnel are carried out It may be remembered that it was proposed to drive a heading with an inclination of 1 in 80 down hill from the shore at each side for a distance of two miles, and then to continue the excavations with a rising gradient of about 1 in 2000 to the centre of the Channel This would probably mean, that part of the tunnel situated under the sea would lie within the Middle Chalk, and would, therefore, cross the fissures at a rather low angle in strata known to allow the passage of water in increased quantities This difficulty might perhaps be overcome by driving the tunnel at each end into a lower geological formation, namely, the Gault Clay This is a point worthy of serious consideration by the engineers If this plan were followed, the highest point at the centre of the tunnel would probably lie within the drier Lower Chalk

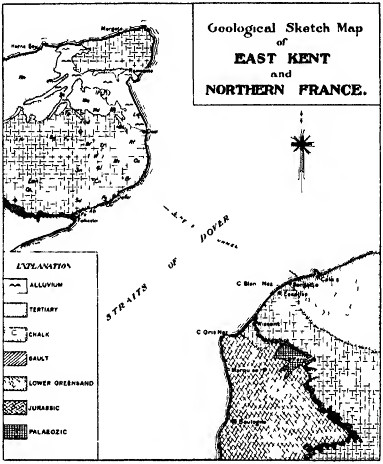

FIG 3

It is probable that in earlier discussions the Gault formation was given less consideration in the belief that it was overlain by water-bearing Upper Greensand, in fact the majority of existing plans show a narrow stippled band between the Gault and the Lower Chalk to represent a supposed outcrop of Upper Greensand Now it has been clearly shown as a result of palæontological investigation that the clay beds IX to XIII of later classifications of the Gault at Folkestone, and their equivalents at the south end of Blanc Nez, represent in argillaceous facies the sandy beds of the Upper Greensand of the west of England Consequently, if the headings at Dover and Blanc Nez were to be driven in the Gault at about the horizon of Bed IX, the workings would lie in argillaceous beds, and the risk of meeting a considerable volume of water would in this way be greatly reduced

As a final remark, it may be suggested that precautionary measures should be taken by the engineers against the possibility of meeting drift-infilled valleys in the Chalk underneath the Straits of Dover The geological chart showing the outcrops of the subdivisions of the Cretaceous rocks on the floor of the Channel, which was made by MM Potier and A de Lapparent as a result of more than 7000 soundings, certainly does not reveal any trace of former valleys in this region, nor has any recent evidence of their existence been obtained, but the fact that many such infilled valleys in the eastern counties of England have been shown to reach depths of more than 300 feet below Ordnance Datum emphasises the need for caution, since such a valley would probably carry a considerable body of water

Work of the Medical Research Council [1]

The report of the Medical Research Council for the year 1927–28 again indicates the wide range of the researches initiated or helped by the Council As in previous years, the work carried out has been aided by grants from various public bodies, including the Dental Board of the United Kingdom, the Miners' Welfare Fund, the Empire Marketing Board, the British Empire Cancer Campaign, and the Distemper Research Council of the *Field* newspaper, as well as by private benefactions At the same time the economy and efficiency with which the available funds are expended are greatly increased by the facilities of the university and other laboratories which are placed at the disposal of workers receiving salaries or grants in aid Of the Parliamentary grant of £148,000, 6 per cent only was absorbed by administrative expenses, £52,000 was provided for the National Institute for Medical Research at Hampstead and the associated farm laboratories at Mill Hill, whilst £86,500, with £18,000 from private and public benefactions, was absorbed by research grants in various university and other centres in Great Britain and by the investigations of the Industrial Fatigue Research Board

Sir Archibald Garrod and Prof Dreyer retired by rotation, and their places were filled by Sir John H Parsons and Dr Robert Muir Sir Hugh Anderson died after the close of the year covered by the report, and the vacancy was filled by the appointment of Prof Leathes Dr H H Dale has been appointed director-in chief of the National Institute for Medical Research

Virus Diseases

Work has been continued on the filter passing viruses and their relation to cancer, and on the treatment of this disease Gye has continued his work on the fowl tumour, in part in association with J H Mueller of the Harvard Cancer Commission, both in Great Britain and in the United States The original experiments indicated that the cell free filtrate by which the growth can be transmitted contains a self propagating virus and a chemical factor the virus could be destroyed by chloroform or acriflavine in serum, whilst the chemical factor disappeared on keeping or warming the filtrate Unfortunately, more recent experiments have failed to give consistent results, treatment of the filtrate either destroying both virus and chemical factor, or failing to destroy the former the inconsistency is presumably caused by the difficulty of obtaining filtrates with uniform properties The disappearance of potency in the filtrate on incubation is due to the presence of an oxidising ferment it can be checked by the addition of hydrocyanic acid, cystein, or reduced glutathione Gye has also found that the filter-passing organism of pleuropneumonia of cattle is destroyed by acriflavine and that the antiseptic's action is aided by the addition of serum, which has an inherent destructive action upon the virus

During the past seven years the outlook for the radium treatment of cancer has been quite transformed definite technical methods have now been worked out for almost every region of the body except the stomach It is already possible to say that early cancer of the neck of the womb can be removed by a course of radium treatment as surely as by the knife, and of course with less suffering and risk Radium is also the best means of treating 'inoperable' cancer of the mouth or tongue, and will probably soon replace excision for the early cases, since it removes the growth without mutilation and with less scarring, and gives a good functional result It seems probable that similar advances will be made in the treatment of cancer in other regions of the body Advance in the use of radium will become more rapid as confidence in its efficacy in the treatment of early cases is gained, as the supply of radium is increased and as the realisation that every treatment centre must be a research centre also and vice versa is generally accepted The report states that the time has now arrived when radium treatment must be put within the reach of all whose lives depend upon it, but this requires a greatly increased supply of radium and an increase in the number of skilled operators and beds available

Work has been continued upon cell growth with the view of elucidating further the nature of tumours and the effects of various agents upon them J A Andrews found that growth *in vitro* of both normal embryonic and malignant tissue is associated with an increase in the hydrogen ion concentration of the medium, and that both tissues *in vitro* are acid in relation to normal adult tissue It might be suggested tentatively that the incidence of malignant disease depends upon the presence of an optimum hydrogen ion concentration coinciding with an autolysate resulting from focal cell death, which acts as the growth promoting agent Helen Chambers, in investigations on the effects of tumour products upon tumour growth, has shown that if the tumour is excised three or four days after irradiation with a lethal dose of the X ray *in vivo*, the animal has absorbed something which confers protection, although the blood contains no immunising power for another animal, and a cell free extract of the excised tumour cannot confer immunity It appears that the antigen producing immunity is absorbed in minute quantities over a period of several days, so that its isolation in concentrated solution is difficult

J R Perdrau has studied that form of encephalomyelitis which is occasionally, though very rarely, associated with vaccinia, as in the ordinary vaccination against smallpox This type appears to be quite distinct from encephalitis lethargica (sleepy sickness) and from poliomyelitis (infantile paralysis), but is identical with that associated with certain

[1] Committee of the Privy Council for Medical Research. Report of the Medical Research Council for the year 1927–28. (London H.M. Stationery Office 1929) 3s net.

acute infections such as measles or smallpox, and with results, also rare, found after antirabic inoculations by Pasteur's method Hence the rare post vaccinal encephalitis is not directly due to the vaccinia virus

The work on canine distemper, already referred to in these columns, by P P Laidlaw and G W Dunkin, has reached the stage of practical application, and numbers of dogs have been inoculated against the disease 73 animals from various packs of foxhounds and 300 dogs of other breeds have been inoculated, but only one contracted the disease in a mild form, although most were exposed to infection Of 170 uninoculated foxhounds which caught the disease, 74 died

The investigations on virus diseases have had another application in quite a different direction Yellow fever is now known to be a virus disease Hindle, adapting the methods devised by Laidlaw and his colleagues succeeded in protecting monkeys against the disease, and the method has already been used in stamping out a local epidemic in Brazil Such a result justifies fully the experimental investigations on canine distemper, quite apart from any practical benefits gained for the dog

ARTIFICIAL LIGHT THERAPY

Some carefully controlled experiments on treatment by artificial light have been carried out by Dora Colebrook on school children No beneficial results were observed light had no influence on gain in weight, height or 'spirits' and the incidence of 'colds' was slightly higher among those receiving the treatment The report critically reviews the results of light therapy and concludes that its sole justifications are in the treatment of rickets and chronic infections such as tuberculosis and, by local application in cases of corneal ulcer or lupus, and possibly varicose ulcers Irradiation of the skin produces vitamin D, from the ergosterol present, and increases the bactericidal power in shed blood, but this increased power has not been correlated with any permanent effects of value to the body, and in any case is quickly followed by a decrease, and the bactericidal power may actually fall below the normal level Moreover, exactly similar effects can be produced by other skin irritants such as a mustard plaster In the case of rickets, the administration of vitamin D by mouth has exactly the same effect as irradiation of the skin by ultra violet light, and since the vitamin can now be prepared synthetically by irradiation of ergosterol and administered in highly concentrated solution, there appears no reason to use artificial light to supply what can be given in the food or as a medicament, especially as the method of oral administration is very much cheaper and more generally available

Sunlight therapy in surgical tuberculosis is undoubtedly very beneficial, but this treatment includes exposure to the open air and also to the longer light and heat rays of the sun, and cannot be strictly compared with a treatment indoors from a source of ultra-violet rays It appears urgent that light clinics should carry out carefully controlled trials of the effects of exposure in the treatment of various conditions

The volume of work on the vitamins carried out during the past year will be separately reviewed later in these columns

TUBERCULIN TEST

The method of detecting tuberculosis in cattle has been improved The 'subcutaneous' tuberculin test has been found to be inconvenient, often fallacious and always difficult to interpret The 'double intradermal' test is simple and convenient, trustworthy and unambiguous, and has now been generally adopted As a by product of this work, G W Dunkin has devised a diagnostic agent for Johne's disease of cattle, a slow wasting disease leading to emaciation, loss of milk, and finally death There is no known cure and no effective means of control except early detection and removal of infected animals The test can be made concurrently with the tuberculin test and has revealed the great prevalence of the disease among stocks in Great Britain its chief danger is in the diminution of the milk supply which results from infection By early diagnosis infected animals can be removed and fattened for killing, and herds kept free from the disease The Council points out that, apart from its indirect hygienic value, this work will save to the agricultural community, in the future, more in a year than has been expended on all forms of medical research supported by the Council during all the years of its work from the beginning

EPIDEMIOLOGY

In investigations on experimental epidemiology carried out on a mouse population kept under continuous observation for eight years, W W C Topley and M Greenwood have found that in each epidemic period the expectation of life of the survivors has been more closely correlated with the length of previous exposure to risk than with the severity of that risk as judged by the average death-rate This suggests that the active immunisation from non fatal infection is a more important factor in increasing the average resistance of survivors than the elimination, by death, of susceptible animals It has also been found that pasteurellosis, an infection primarily of the respiratory tract, and mouse typhoid, a typical intestinal infection, show a definite difference in their epidemiological behaviours, which may be of great significance

L Hill and his colleagues have found that spraying hypochlorite solution into the air of a room or circulating the air through oiled baffleplate filters definitely diminishes the number of microbes present the experiments provide justification for the use of sprays in crowded public rooms

H Burt White has found that there is a close correlation between a positive Dick test and subsequent puerperal sepsis in pregnant women The test is used to indicate susceptibility to scarlet fever, but also indicates susceptibility to the toxins of other strains of streptococci, including those from puerperal fever Arrangements have been made

to carry out an extensive trial of the results of rendering Dick positive subjects immune to puerperal fever before labour

Biological Standards

In concluding this review of some of the important subjects dealt with in this report, reference may be made to the work on biological standards, which has an international importance The first British standard tuberculin has been adopted as the international standard by the Permanent International Standards Commission of the League of Nations Health Organisation its strength is equivalent to that of the standard originally created by Ehrlich The adoption of an international standard of dried scarlatina antitoxin necessitated the production of an equivalent British standard but the method of measuring the potency of an antitoxic serum by its neutralising action on the toxin, as tested by the human skin reaction, cannot discriminate between antitoxins differing from each other by less than 100 per cent Recently, Hartley has succeeded in concentrating the toxin so that its lethal dose for the rabbit can be accurately measured and an adequate number of lethal doses used in the neutralisation test A British standard digitalis powder is in course of preparation and will be made to conform with the international standard already in existence An international physical unit of X ray dosage has also been defined and adopted and agreement reached on the principles governing its standardisation the connexion between physical dosage and biological effect is still being studied

Obituary

Dr T B Osborne

THOMAS BURR OSBORNE, who died on Jan 29, was the last of the small band of pioneers who laid the foundation stones of modern protein chemistry Born in New Haven Connecticut, on Aug 5, 1859, of old New England stock, he graduated after the usual course in arts at Yale College in 1881 Turning his attention to analytical chemistry, he took the degree of Ph D in 1885, and a year later joined the staff of the Connecticut Agricultural Experiment Station in New Haven Prof Samuel W Johnson, director of the Station and professor of agricultural chemistry at Yale, suggested that Osborne should extend Ritthausen's early work on vegetable proteins, and in 1888 he started investigations which continued without interruption until his retirement in 1928

From 1890 until 1901 Osborne's chief interest was in the preparation of pure specimens of the seed proteins, and his initial investigation of the oat kernel, published in 1891, was the forerunner of a series of papers in which the proteins of thirty two different seeds were described These researches demonstrated that proteins could be regarded as definite chemical individuals and that many substances formerly grouped together under such terms as 'legumin,' conglutin,' and vitellin' differed in chemical composition as well as in physical properties His conception of the protein molecule as a definite chemical entity was strengthened by his work on the acid binding power of edestin, published in 1899, and by later papers in which it was shown that proteins in general could form salts with both acids and bases, and that they were capable of electrolytic dissociation

Working as he did in close contact with agriculture, Osborne early realised the need of a chemical characterisation of proteins which would give some index of nutritive value, but characteristically deferred any such research until he was convinced that he could first obtain proteins in the highest state of purity Taking full advantage of the developments in analysis due to Kossel and Fischer, he commenced in 1906 a series of protein analyses which demonstrated that wide differences existed in the amino acid composition of many proteins of economic importance These analyses were made with Osborne's usual extreme care, and were the basis of his future work on the nutritive value of the proteins, begun in collaboration with Prof Lafayette B Mendel of Yale, in 1909, and continued with the generous support of the Carnegie Institution of Washington until the time of his death

The results of Osborne's protein investigations were summarised in a monograph 'The Vegetable Proteins, which was published in 1909, and extensively revised in 1924 His life was devoted almost entirely to his research, and, unlike most investigations, increasing years and fame brought no increase in administrative responsibility, consequently until the last his working hours were spent in the laboratory, and those who were privileged to work with him and gain his confidence found in him not only a genial friend and stimulating critic, but also a man with an unsurpassed wealth of practical experience in his own particular field of science

Osborne was a member of the National Academy of Sciences, an honorary Sc D of Yale, and an honorary fellow of the London Chemical Society Last year the American Association of Cereal Chemists instituted the periodic award of the Thomas Burr Osborne medal for distinguished research in cereal chemistry, and he was himself the first recipient

We regret to announce the following deaths

Dr Paul Dvorkovitz, a well known petroleum technologist, aged seventy two years

His Highness Sir Bhawani Singh Bahadur, K C S I, Maharaj Rana of Jhalawar, who was well known in scientific circles in Great Britain and was a delegate from India at the two hundred and fiftieth anniversary of the Royal Society, on April 13, aged fifty four years

Prof John MacCunn, emeritus professor of philosophy in the University of Liverpool, on Mar. 24, aged eighty two years

News and Views.

PROF D'ARCY THOMPSON'S presidential address to the Classical Association on April 8 at Cardiff is a welcome reinforcement of the plea so often advanced in these pages for a closer alliance between the humanities and science It is the more welcome because it approaches the subject at an unaccustomed angle and in a fresh spirit of hopefulness and enjoyment Whereas we are always thinking, and have often said, how necessary is some knowledge of history to the man of science and some knowledge of science to the historian and man of letters, and how deplorable is the general lack, Prof Thompson boldly takes the cheerful line "From time immemorial science and the humanities have gone hand in hand Aristotle wrote on poetry and Plato loved astronomy And at the Renaissance all the scholars read Galen and Hippocrates" It was the natural thing, and, though the vast extension and specialisation of knowledge now make it more difficult, it is still the most stimulating and pleasurable way to widen and deepen our intellectual associations It is, of course, all that, on the side of personal culture, and far more on the side of civilised life and social continuity Nothing is more important for the future, if mankind is to rise above the pleasures, the problems, and the whirl of the present, than to go back and find the roots of our thought, the first impressions of the wonder and order of the world, in the works of the earliest thinkers who have expressed them for us Socially and philosophically, this sense of filiation and indebtedness is even more valuable than the idea of solidarity with those now living which is now constantly dinned into our ears by the multitude of international associations, from the League of Nations downwards

IN spite of his cheerful tone, one must sorrowfully admit that Prof D'Arcy Thompson is one of a very small band of persons now alive qualified to act as liaison officers between the two camps of science and humanity Scholar and naturalist, he has written a glossary to the 'Birds' of Aristophanes, of which he spoke at Cardiff with such well merited enthusiasm Prof Arthur Platt was another, approaching the matter with the outlook of the Greek scholar The essay which occurs to us as most in sympathy with Prof D'Arcy Thompson's address, and worth reading after it, is Platt's chapter on "Aspects of Biological and Geological Knowledge in Antiquity" in "Science and Civilization," the sixth volume in the Unity Series Unfortunately, it was not reprinted in Platt's posthumous Nine Essays but it is delightful in style and fits in admirably to the sketch which Prof D'Arcy Thompson gave last week Some day perhaps the Classical Association will form a subsection for the study of classical science.

EVERY year marks a further advance in the steady progress of civil and military aviation In great measure this is due to the fact that, almost alone in the field of applied science, research and practice in this case can run hand in hand While the expenditure on air armaments, however, has been bounding up in other parts of the world, the net expenditure of Great Britain for the fourth year in succession, according to the Air Minister in introducing his estimates for 1929, shows a decrease, this in spite of the ease with which it has been demonstrated how vulnerable England is to attack from the air At the end of the year the strength of the Air Force will have been raised from 75 to 82 squadrons, a figure considerably below that of several other great powers On the civil side, this year will mark a notable stage in the development of imperial air communications A regular air service to India has already begun, the first outward journey being completed within 150 minutes of the scheduled time, and the return journey almost exactly on time It is intended to run a weekly service, doing the journey in from six to seven days Meanwhile steps have already been taken for the inauguration of the other great trunk line service—London to the Cape For some years past, units of the British and South African Air Forces have been making service flights over the routes and collecting data, while particularly during the last twelve months much pioneer work has been done by Sir Alan Cobham, Lady Heath, Lady Bailey, and Captain and Mrs Bentley The result has been to provide experience and information without which the regular flight of 6245 miles from north to south would be quite impracticable Every colony and dominion in South Africa is certain to derive great benefit from this venture North and South Rhodesia, for example, at present three weeks from London, will come within ten days' journey, and the Union Parliament at Cape Town will be within twelve days of Westminster The ultimate success of the scheme depends on the financial aid forthcoming from the other Governments concerned

THIS year's air estimates for Great Britain provide for a number of developments of a technical nature Two aircraft are to be specially constructed to test the relative merits of monoplane and biplane, particularly for civil aviation The all metal plane, which has been the subject of intensive study for some time, is now coming into its own Four years ago the Air Ministry was ordering one metal machine for every nineteen of wood construction To day the orders are seven metal machines for one wood, so swift and complete has been the revolution in the methods of construction during the past four years In introducing his estimates, Sir Samuel Hoare paid a tribute to the brilliant work of the experimental pilots at Farnborough and Martlesham and the special efforts of the Aeronautical Research Committee Not the least significant of his announcements was his statement of a proposed grant to the recently formed National Flying Services Company, a step, it is hoped, that will stimulate the air sense of the nation This grant is dependent on the provision, directly or indirectly, of one hundred new aerodromes and landing grounds There can be no doubt that the next few years will witness an enormous speed up of civil and commercial flying in Great Britain

At the meeting of the Royal Meteorological Society on April 17, Dr J Glasspoole gave some details of the scanty rainfall of the first three months of the year The total precipitation over the British Isles during these months was only half as much as usual and less than that of any similar period in the last sixty years of comparable data, the nearest approach being that of 1891, with 60 per cent of the average amount The drought of 1929 was most intense in Great Britain in four well marked areas, each of which received less than one third of the average These areas included a narrow strip across the Thames Valley from Gloucester to Margate, Central Wales, the English Lake District, and much of the northern half of Scotland The fall at stations in these regions was as follows

	Rainfall (in)	Per Cent of Average
London (Camden Square)	1 5	29
Borrowdale (Seathwaite)	9 7	27
Rhayader (Tyrmynydd)	4 2	25
Alness (Ardross Castle)	2 2	22

At Ardross Castle the period included both the driest January and the driest March of the last sixty years, and the total rainfall was less than that of any other three consecutive months The total for January to March at Gloucester was only 1 27 in, and at Shoeburyness only 1 18 in Less than 2 in was recorded at stations in the Midlands, near Oxford and London, and in the neighbourhood of the Moray Firth There was less than 3 in during the three months over nearly half the total area of England and Wales including central and south eastern districts One of the main features of the weather was the marked weakening of the south west winds and consequent deficiency of rainfall in the mountainous regions Parts of the English Lake District and the Western Highlands of Scotland received 25 in less than usual during this period

Holborn recently acquired an unenviable notoriety in being, on Dec 20 and 21 last, the scene of a series of street explosions and fires which took place on a line beginning at the junction of Kingsway and High Holborn, and proceeding westwards along High Holborn, Broad Street, and High Street to St Giles's Circus With commendable promptitude the Home Secretary on Dec 21 appointed a Commission consisting of Mr R G Hetherington, Lieut Col R A Thomas, and Mr E H Tabor, with Mr A S Hutchinson as secretary, to inquire into the circumstances of the explosions and fires, the Commission, which commenced its investigations on the following day, has now issued its Report (H M Stationery Office, Cmd 3306, 1s 6d net) It is concluded that the explosion occurred in the Post Office tube (an old pneumatic parcels tube now otherwise employed), that it was due to a mixture of coal gas and air, that the gas probably resulted from gradual accumulation, together with an escape sufficient to increase the concentration to the explosion limit, and that the gas became ignited in a manhole through some action (probably the use of a petrol lighter) by a workman

In its investigations concerning the nature of the explosive agent, the Commission examined three theories that the gas was coal gas, petrol vapour, or gas arising from anaerobic fermentation The petrol vapour theory was rejected after elucidation of the facts that no odour of petrol was perceptible and that there was no black smoke or luminous flame The theory that the explosion was due to the presence of fermentation gas was carefully studied Evidence regarding the odour was conflicting, none of the samples of gases collected from the ground after the explosion, however, contained methane and carbon dioxide as the chief constituents, whilst all contained oxygen in quantities which negatived the possibility of anaerobic conditions Moreover examination of the subsoil demonstrated that the conditions were aerobic, and the production of anaerobic gas on the requisite scale would have involved sewage decomposition in unacceptably large quantities Alone, the coal gas theory was consistent with all the facts Recommendations concerning ventilation and gas leakage are made, it being suggested that underground cavities, including manholes, should be either continuously ventilated or filled in, that the use of a continuous gas detector would be desirable, and that the gas company concerned should strengthen its organisation for the detection of leakage

Dr A D Little, president this year of the Society of Chemical Industry, who intends to sail for England on June 15 in order to preside over the annual general meeting at Manchester on July 9, has sent a personal message to American and Canadian members of the Society expressing the hope that many will take advantage of the opportunity of consolidating the friendships so happily begun at the meetings of last year and establishing new ones under peculiarly favourable auspices The Raymond and Whitcomb Co, which is dealing with transport arrangements, points out that June 28 and 29, the last sailing dates which will assure members reaching Manchester in time for the opening meetings, are the heaviest of the entire season, so that early notification of probable requirements is necessary The programme in connexion with the annual general meeting commences on Monday, July 8, and continues until Saturday, July 13, it includes addresses by the president, by Prof Pear, and by Sir Richard Threlfall, visits to works, excursions, the annual dinner, and a number of social gatherings American chemists and chemical engineers who may find it possible to visit Great Britain in connexion with these meetings may be assured of a cordial welcome from their British colleagues, by whom the occasion is being anticipated with much pleasure

In opening a discussion at the Society for the Study of Inebriety on alcohol in therapeutics on April 9, Dr J D Rolleston said that from the earliest times the subject has given rise to acrimonious discussions in the medical profession On the introduction of distilled liquors into medicine in the thirteenth

century, the new remedy was regarded as a panacea and as an elixir of life, as was shown by the terms *aqua vitæ* and *eau de vie*, though the designation of *eau de mort*, used by Voltaire several centuries later, appeared more applicable. The remarkable decline in the therapeutic use of alcohol within the last thirty years is best illustrated by the fall in the alcohol bill in various hospitals, but is also shown by the practice of individual physicians and the small place which alcohol now occupies in modern text books of medicine compared with those of forty years ago, when the writers, still imbued with the medieval doctrine, extolled the therapeutic value of different alcoholic beverages in a great variety of diseases. At the present time in the United States only a minority of practitioners have applied for a licence in those States in which the right to prescribe alcohol is granted. The conditions in which alcohol is still chiefly employed are pneumonia, enteric fever, diphtheria, and other acute infections, diabetes, heart disease, tuberculosis, inoperable cancer, and senility, but it does not appear to be indispensable in any of them. In conclusion, Dr. Rolleston maintained that the factors chiefly responsible for the undeserved esteem which alcohol still enjoys as a therapeutic agent are tradition, rather than scientific evidence, extra-medical influences, and personal considerations.

All cities in the world with populations of more than half a million are being faced with the problem of transporting large numbers of workers daily from one section of the city to another. For London, Captain Swinton and Col. M. O'Gorman are advocating a raised ring road 15 miles in circumference which would pass near the eleven railway termini and Earl's Court. According to an article in the *Westinghouse International* for May, considerable relief for congested traffic can be obtained by using modern electric cars operating in subways or on overhead tracks. Some of the new cars are more than 42 feet long and weigh 15 tons. No other vehicle can haul so many people with equal safety at such a low fare. In America, in one city alone the inauguration of a new electric rapid transit system is calculated to save one hundred thousand passengers one hour daily. Cars are now made to accommodate 104 passengers comfortably, fifty horse power motors being used. Trackless trolley buses are also successfully operated in many cities in the United States. They are of the six wheeled type, weighing about 8 tons, using fifty horse power motors and taking their power from an overhead 600 volt trolley wire. A large number of petrol buses are now being supplied with electric equipment which usually consists of a generator and one or two motors. It is claimed that these petrol electric vehicles have many advantages over those operated purely mechanically. They accelerate much more smoothly, and owing to the absence of gears there is very little noise. These improvements are the result of long continued experimental researches.

The Manson Medal of the Royal Society of Tropical Medicine and Hygiene, awarded triennially, is to be presented this year to Sir Ronald Ross. It was founded in memory of Sir Patrick Manson in 1922, and has been awarded to Sir David Bruce and Senator Ettore Marchiafava. Qualifications for the medal are contributions of outstanding merit to knowledge of tropical medicine and hygiene. The Chalmers Medal, which was founded in 1921 by Mrs. Chalmers in memory of her husband, Dr. Albert J. Chalmers, is awarded every second year to the younger workers in the field of tropical medicine and hygiene, who must be under forty five years of age on June 1 of the year of award. It is to be presented this year to Major J. A. Sinton; previous awards have been to Prof. E. Roubaud, Prof. Warrington Yorke, and Dr. H. Lyndhurst Duke. Though the Manson Medal was founded in memory of Sir Patrick Manson, the Society is endeavouring to found a more substantial memorial in the shape of a permanent home for the Society. To this end the 'Manson House' Fund was started, and already donations have brought in £4373, while £3000 have been promised on loan without interest. It is hoped that a sufficient sum will now soon be raised to enable the Society to purchase suitable premises which will form the headquarters of the Society and will be named after Sir Patrick Manson, the first president of the Society.

The tenth annual meetings of the American Geophysical Union and of its sections will be held in the National Academy and Research Council Building, Washington, D.C., on April 25 and 26. Following the business meeting of the general assembly of the Union on the afternoon of April 26, the Union will hear the five following general interest papers, all relating to current or recent work, presented by the Section of Oceanography: The expedition of the submarine S21 to the Caribbean Sea and Gulf of Mexico, by C. S. Freeman; oceanography and the fisheries, by Henry B. Bigelow; the international ice patrol, with special reference to its economic aspects, by Edward H. Smith; the co-operative survey of the Great Lakes, by Charles J. Fish; the work of the *Carnegie* to date, by W. J. Peters. The six sections, dealing respectively with geodesy, seismology, meteorology, terrestrial magnetism and electricity, oceanography, and volcanology, will hold short business meetings to be followed immediately by progress reports and scientific papers. The scientific sessions will be open to persons interested in geophysics, whether members of the Union or not. These annual meetings are increasingly interesting each year, not only because of the stimulus afforded the study of problems concerned with geophysics, but also by reason of the co-operation of the corresponding geophysical organisations of Canada and Mexico, which is making for initiation and co-ordination of geophysical researches depending upon international and national co-operation.

In the course of his presidential address to the Institution of Professional Civil Servants at the annual general meeting on April 12, Sir Richard Redmayne dealt with the position of the technical expert in the civil service. He referred to the claim which the Institution is putting forward on behalf of scientific

members of the Civil Service, of whom, thanks to the understanding it has recently reached with the Association of Scientific Workers, it is fully representative The claim is not just a demand for 'more money', it is based upon the thesis that a modern State must accord to the scientific worker a status and a sphere of influence as high and as extensive as are enjoyed by those whose duty it is to take what is usually known as 'the decision' The case of the scientific worker is, however, only one aspect of a much larger problem, namely, the status of the technical expert in public administration The Institution is of opinion that the watertight division between 'administrators and technical advisers' is leading to inefficiency and waste owing to the absolute power placed in the hands of the administrator to determine matters of policy in regard to which technical considerations may be paramount At the present time the organisation of the Civil Service is on the basis of the needs of departments of State some two generations ago The reorganisation of the Service in the light of scientific progress is of such vital public importance that it calls for an inquiry by a public body The Institution, the chief aim of which is increased efficiency of the public service, will not rest content until such an inquiry has been made

Sir Hubert Wilkins intends to return to the Antarctic in September to continue his explorations by aeroplane He has given an account of his plans in the *Times* From Deception Island, where his Lockheed machines are now stored for the winter, he and Lieut Eielson will fly south to Hearst Land along the western coast of Graham Land On this long flight no landing place is assured, for the coasts are rugged and the sea will be open, but strewn with ice Sir Hubert suggests that tabular icebergs might afford emergency landing places On the other hand, they may not be available On Hearst Land a depot will be made, and there the aviators will await reports of favourable weather conditions from the whalers and Commander Byrd in the Ross Sea before starting on the flight of 2000 miles to King Edward Land along the unknown coast line of Antarctica This must be a risky flight, for conditions are entirely problematical, but it should be possible to cover the distance between successive blizzards Sir Hubert hopes to locate a suitable site for a meteorological station, and in any event he will, if successful, add a considerable stretch to the coast line of Antarctica

Mr A M Daniel, director of the National Gallery, Dr Cyril Norwood, headmaster of Harrow School, and Mr W J Tapper, president of the Royal Institute of British Architects, have been elected members of the Athenæum under the provisions of Rule II of the Club, which empowers the annual election by the Committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for public service

We are informed that, as a result of a recent meeting, a body has been constituted under the title of the "Ultra Violet and Allied Trades Association," consisting of a number of the leading firms engaged in the design, manufacture, and marketing of ultra violet, physio therapy, and other electro medical apparatus in Great Britain The Secretary of the Association is Mr C Rodgers, and the offices are at Kern House, 36 Kingsway, London, W C 2

The Swedish Government has placed an order with the Marconi Company for the supply of a 60 kilowatt aerial energy transmitter for installation at Stockholm The fact that this contract was obtained by the Marconi Company in the face of keen competition is a tribute to the excellent design and performance of British broadcasting transmitters already installed in more than twenty countries outside Great Britain The new Swedish broadcasting station will be effective over a very large area It will be operated on the low power modulation system with deep and distortionless modulation, and will be worked direct off a three phase public electric power supply

Mr H V Garner and Capt E H Gregory will again be available to demonstrate the Rothamsted and Woburn Experimental Plots during the summer to farmers and other bodies interested in agriculture or market gardening At Rothamsted the soil is heavy The experiments deal with the manuring of arable crops, grazing land, and hay land with crop diseases and pests, and with new methods of laying down of land to grass At Woburn the soil is light The experiments there are concerned more particularly with the manuring of potatoes, sugar beet, wheat, malting barley, and the use of green manures Communications should be addressed to the Secretary, Rothamsted Experimental Station Harpenden

A catalogue (No 167) of second hand books of science, ranging over most branches, has just been published by Messrs Dulau and Co, Ltd, 32 Old Bond Street, W 1 It can be obtained free upon application There are upwards of 1400 items listed and the prices asked appear very reasonable

Applications are invited for the following appointments, on or before the dates mentioned —A general engineering master at the Acton Junior Technical School—J E Smart, Municipal Offices, Acton, W 3 (April 27) An inspector under the Ministry of Agriculture and Fisheries for the purposes of the Diseases of Animals Act, 1894–1925—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S W 1 (April 29) A second assistant in the County Analyst s Laboratory, Derby—The County Analyst, County Offices, St Mary's Gate, Derby (April 29) Two assistants on the higher technical staff of the Victoria and Albert Museum—The Director and Secretary, Victoria and Albert Museum, South Kensington, S W 7 (May 4) A lecturer in civil engineering and building trades work in the engineering department of the Portsmouth Municipal College—The Secretary, Municipal College, Portsmouth (May 4) A lecturer in economics at the City of Birmingham Commercial College, with special qualifications in transport subjects—The Principal, City of Birmingham Commercial

College, Suffolk Street, Birmingham (May 4) A workshop instructor in carpentry and joinery at the Birmingham Central Technical College—The Principal, The Central Technical College, Suffolk Street, Birmingham (May 6) A technical officer for the Air Ministry Technical Development Staff, primarily for work at the Royal Air Force Base, Gosport, in connexion with the development of torpedoes for aircraft use—The Secretary, Air Ministry (S 2) (quoting B 335) (May 11) A research assistant in the department of coal gas and fuel industries of the University of Leeds, for work in connexion with the Joint Research Committee of the Institution of Gas Engineers and the University—The Registrar, The University, Leeds (May 12) A post in the zoological department of the University of Manchester—The Registrar, The University, Manchester (May 14) A professor of physiology in the University of Bristol—The Secretary, The University, Bristol (May 16) An assistant lecturer in physiology in the physiological department of the University of Birmingham—The Secretary, The University, Birmingham (May 31) Probationers for the Indian Forest Service—The Secretary, Services and General Department, India Office, S W 1 (July 1) An assistant in the mechanical engineering section of the Engineering Department of the Halifax Municipal Technical College—The Principal, Municipal Technical College, Halifax A medical woman with experience in teaching anatomy, to act for the professor at the Lady Hardinge Medical College, New Delhi—The College Principal, Lady Hardinge Medical College, New Delhi, India A laboratory steward in the physics department of the Military College of Science, Woolwich A qualified technical chemist at the Stores Inspection Department of the Office of the Crown Agents for the Colonies—The Crown Agents for the Colonies, 4 Millbank, S W (quoting O/Sec Office 91)

Our Astronomical Column

The Radius of Space—The following cablegram (which has been somewhat expanded from its very concise telegraphic wording) was received from Dr Ludwik Silberstein on April 10 "A star formula which is developed in the course of my monograph 'The Size of the Universe,' now in course of publication at the Oxford University Press, when applied to 35 stars of type O yields for the radius of space the value 3 2 × 10^{11} astronomical units, when applied to 29 Cepheids, 3 0 × 10^{11}, and when applied to the 246 more distant stars of Young and Harper's list, 3 4 × 10^{11} units The latter computation was completed on April 7, its agreement with the two former ones definitely establishes that space is finite, and that its radius is thirty trillion miles (in the British use of the term), or about five million light years"

The Einstein theory has familiarised us with the idea of space being limited and re entrant into itself, the surprising point in the above communication is the much smaller value that is assigned to the radius than has been found by other methods It is, indeed, only a small fraction of the estimates of the distances of the fainter spiral nebulæ that have been assigned in recent years by Profs Hubble and Shapley, these go up to 140 million light years The acceptance of Dr Silberstein's value would mean a drastic revision of the whole method of determining distances by the periods and apparent magnitudes of Cepheid variables, assuming its truth for the moment, we note that the two spirals, the distance of which Hubble found to be about a million light-years (the Andromeda nebula and Messier 33), should also be visible in the opposite direction, since their distance by that route would be only nine times as great as by the shorter route, it so happens that there are conspicuous nebulæ very near the opposite points—*h* 3433 and Messier 83 respectively, their positions for 1860 are respectively R A $12^h\ 44^m\ 37^s$, S Decl 40° 18 7′, and $13^h\ 29^m\ 9^s$, S 29° 9 0′ The appearance of Dr Silberstein's monograph will be awaited with interest, but in the meantime his announcement will necessarily be received with some reserve

The Spectrohelioscope—Prof G E Hale, the inventor of the spectrohelioscope, contributes an article upon it to the *Scientific American* for April, he shows that it is not a mere toy, designed to enable the eye to discern features that could be equally well studied by photography, in fact, in several respects it gives the observer powers of study much greater than those afforded by the photographic plate This only records the aspect at a single instant, whereas the observer with the spectrohelioscope can quickly detect the most active regions of the disc, and follow the changes continuously Prof Hale says "I have frequently seen the swift flow towards sunspots of masses of hydrogen larger than the earth, adequately recorded with the spectroheliograph only once in twenty years"

Prof Hale goes on to describe a further improvement, the 'line shifter', this is an adjustable plate of plane glass behind the second slit, which permits the observer to set different parts of the width of the line on the slit in quick succession, this gives information about the radial motions in different regions of the formation One side of an arch may be seen to be rising, while the other is falling Prof Hale has prepared instructions whereby a handy person can construct a spectrohelioscope at a cost "comparable with that of a fine radio set"

Greenwich Observations of the Sun and Planets—The Astronomer Royal and Mr R T Cullen contribute a paper on this subject to the January number of the *Monthly Notices* of the Royal Astronomical Society The study of the solar observations is carried back to those of Bradley, beginning about 1750 It was found that early observations of the sun in right ascension were subject to large errors, those in declination appeared to be more satisfactory Accordingly, the error in longitude has now been deduced from the observations of declination made near each equinox, this is a similar process to the well known method of Flamsteed for determining the equinox The 'secular acceleration' of the sun is clearly shown by the residuals The coefficient of T^2 is deduced as + 0 78″, which is comparable with that found by Dr Fotheringham The solar residuals show oscillations which accord fairly well in period and phase with those of the moon, but are about one tenth of the amplitude

As regards the outer planets, the residuals of Saturn changed abruptly from + to - at the date of the introduction of the moving wire, 1915 Those of Neptune have been changing fairly uniformly from zero early in the century to - 3″ in 1928 Its latitude also shows progressive change, but not quite so regular

Research Items

A PREGNANCY CUSTOM IN WEST AFRICA.—Dr. J. Maes describes in *Man* for March a recent acquisition of the Musée du Congo Belge from the Katanga which is connected with a child-birth custom distributed through a wide area in West Africa. The object is a clay figurine of a seated female figure holding on her lap a disproportionately large bowl. The stylisation of the hair indicates that the figure represents a woman of the Bena Kanioka. It is the first record of this custom among these people, though figures of this type are common among the Baluba. These figures are made by men during the pregnancy of their wives. When the time of delivery approaches, and the woman is no longer able to work in the fields, the figure is placed at the door of the hut and all passers-by place alms in the bowl. These gifts are shared among the woman's friends when they return at night in return for the produce of their fields which they give the expectant mother, and for labour which they have expended on her garden. This custom is found among the Yoruba, and clay figures made by the peoples of the Gulf of Guinea exhibit exactly the same characters as these from the south of the Belgian Congo.

THE TASMANIAN SKULL.—Prof. Wood Jones (*Jour. Anat.*, vol. 63, pt. 2, pp. 224-232) in a recent paper gives a group of four graphic reproductions of the average or composite skull of the Tasmanian, the first of a series of racial types with which he proposes to deal in turn. The reproductions include the normæ lateralis, facialis, occipitalis, and verticalis, and are based on ninety skulls. The author finds that the whole cranium presents a rounded and well-filled contour which is considerably in advance of that shown in figures usually given in works on physical anthropology. The temporal fossæ are well filled and the vault of the skull evenly rounded in facial view. The forehead is not markedly narrow nor is the vault of the cranium low or long. The cranial capacity, using Lee's formula, averages 1353 c.c., or, using the formula of Broca and Manouvrier, 1424 c.c. This is high compared with the previous estimates of 1220-1230 c.c. The author concludes that the commonly accepted low average cranial capacity in this race, like the reputedly humanly low class features of the cranium, has been wrongly emphasised, with the result that the Tasmanian has been ascribed a lower place in the human scale than the examination of his cranium warrants.

SPAWNING MIGRATION OF SALMON.—A report just received from Russia ("Physico-chemical characteristic of breeding migration fast of Keta Salmon," by Prof. B. P. Pentegoff, U. N. Mentoff, and E. F. Kurnaeff. *Bulletin of the Pacific Scientific Fisheries Research Station*, vol. 2, part 1. Vladivostok, 1928) contains an interesting study of the breeding migration fast of the Keta salmon. It is stated that the total distance traversed by the Amur River autumn salmon during the spawning migration is about 1200 kilometres in the river alone. The information upon the sea portion of the migration is meagre, but on the basis of a single marked fish liberated from the Island of Unda and later recaptured in the River Pankara, Kamchatka, the authors conclude that the sea migration is similar to the river migration, that is to say, in a contranatant direction and towards increased temperature. During this portion of its migration the fish travelled at a rate of 70 kilometres per day for 34½ days, without food. Perhaps the main value of the paper lies in the detailed physical and chemical studies of the fish at all stages of the journey up river, during which the speed of the fish is said to be on the average 115 kilometres per day, and to be in inverse ratio to the speed of the current. A total of 172 fishes (equal numbers males and females) were subjected to minute analysis. From the sea to the time of death after spawning, the males lost 77.21 per cent of their reserves of energy, and females 78.75 per cent. At first the proportion of energy expenditure from the destruction of fat to that from the destruction of protein increases, but this relation is later reversed. It is calculated that the average daily expenditure of energy in their passage up the river is 25,810 small calories for males, and for females, 28,390 small calories, for each kilogram of live weight. Among the more important chemical changes in the muscular tissue are the following. From the sea to the time of death at the spawning ground, the loss of fat was 98.72 and 97.27 per cent in males and females respectively; of proteins, 57.29 and 57.68 per cent; of ash, 47.03 and 47.07 per cent; and of water, 15.18 and 20.74 per cent respectively.

BRYOZOA AND ALGÆ OF MUTSU BAY.—Dr. Yaichiro Okada reports on the cyclostomatous Bryozoa and Mr. Yukio Yamada on the marine Algæ of Mutsu Bay ("Cyclostomatous Bryozoa of Mutsu Bay" and "Marine Algæ of Mutsu Bay and Adjacent Waters, II," *Report* of the Biological Survey of Mutsu Bay, 8 and 9. *Science Reports of the Tôhoku Imperial University*, 4th Series (Biology) Sendai, Japan, vol. 3, No. 4, Fasc. 1, 1928). Both papers are contributions from the Marine Biological Station, Asamushi, Aomori Ken. The Bryozoa in their zoogeographical distribution combine the characteristics of the Pacific boreal sub-region and the Indo-Pacific coastal region. In continuing his work on the marine algæ, Mr. Yamada has himself made extensive collections, adding very appreciably to the knowledge of the flora of the district. Not only does he record and describe many rare forms, but, what is really more important, he also shows that many species are common which were not before known to live there at all. Some of his most interesting finds belong to the Elachistaceæ, growing in pools on fronds of *Sargassum* and *Phyllospadix*. Fifty species of algæ are recorded in the present report, making 86 in all, 6 of which are new.

NON-PROLIFERATING BACTERIA.—In two papers (*J. Hygiene*, 28, pp. 139-46, 1928; and *Ann. de la Brasserie et de la Distillation*, Dec. 10, 1928), Dr. J. H. Quastel sums up the interesting results which he and his colleagues have obtained at the Biochemical Laboratory, Cambridge, by the study of non-proliferating, or, as they were at first less happily termed, resting bacteria. The organisms are used in the form of a suspension under such conditions that practically no growth occurs during the observations, and the chemical changes can thus be studied without complication. The properties of such organisms have been intensively investigated in the case of *B. coli*, which has the power of activating a very large number of substances, that is, rendering them capable of performing chemical reactions, such as reducing methylene blue, which they cannot perform in the absence of the cell. The degree of activation produced varies greatly with different substances, and, moreover, the activating powers towards different substances are very differently affected by varying modes of treatment of the organism. Thus, after treatment with toluene, glucose is no longer activated,

whereas formic acid is as powerfully activated as before the treatment Facts of this kind have led the author to the view that activation of the substrate is not necessarily due to the existence of specific enzymes He suggests that activation, which consists in a polarisation (an internal electrical change) of the substrate molecules, occurs at particular regions or centres on the surface structures (interfaces) of the cell Activation is conditioned by the specific adsorption of the substrate at the activating centre, the constitution of the substrate molecule and the nature and strength of the polarising field This theory is successfully applied to the explanation of the observed phenomena of activation and of the conditions necessary for anaerobic growth

SUGAR BEET TRIALS —The report of the second year trials of sugar beet carried out by the University of Bristol on some thirty three local farms adds very little indeed to the information already available as to the cultivation and manuring of that crop As a wide spread demonstration, this experiment may have served its purpose in giving the farmers illustrations of the cultivation and manuring of what is after all a comparatively new crop, but the results obtained must not be regarded too seriously The trials had a wide range, and covered cultivation, time of application of nitrogen, and the form of nitrogen to be applied, and on the results one draws the general conclusion that a moderate application of one or other of the soluble nitrogenous fertilisers will produce an increase in yield which is sufficiently great to make the practice profitable This cannot be considered as new information, but it may serve to confirm over a considerable area of cultivation the results of smaller individual trials carried out in various parts of Great Britain from about 1877 until the present time It is interesting to notice that the yields obtained in the trials now described are relatively high Even without nitrogen, and over a range of soils including Greensand, Bunter crag, and Old Red Sandstone, an average of 12 2 tons of washed beet per acre was obtained The average obtained by Great Britain as a whole during last season was about 8 tons of washed beet per acre Within this margin, between the eight and the twelve, lies the future of sugar beet growing in England, for unless the return per acre improves it is almost certain that the reduction of acreage which was seen last year will continue in future years and the factories will be unable to find acreage to support themselves If such trials as those reported upon from Bristol serve only the purpose of showing the growers how increased yields may be obtained without undue increase of expense, then they may well find justification for their continued existence

NEW GASTROPOD FROM THE SILURIAN OF ALASKA — From the same Upper Silurian horizon in Alaska whence he obtained the remarkable bivalve *Pycnodesma* (see NATURE, Oct 22, 1927, p 600), Mr Edwin Kirk has now described (*Proc U S Nat Mus* , vol 74, art 18) an equally interesting new gastropod to which the name of *Bathmopterus liratus* has been given The shell superficially resembles *Euomphalopterus*, but has a well defined slit band and is apparently referable to the Pleurotomariidæ, or possibly the Euomphalidæ The specimens here described and depicted came from Willoughby Island in Glacier Bay

MOLLUSCA FROM THE GULF OF CALIFORNIA AND THE PEARL ISLANDS —Mr H P Bingham, of New York, following in the footsteps of the late Prince Albert of Monaco, has been conducting expeditions in his yacht *Pawnee* and forming a collection for the purpose of oceanographic research at the Peabody Museum of Natural History, Yale University, while a *Bulletin of the Bingham Oceanographic Collection* is published in connexion therewith Although the primary object has been ichthyological research, other branches have not been passed by altogether, and Lee Boone describes in the *Bulletin* (vol 2, art 5) the mollusca dredged in 1926 during an expedition to the Gulf of California and the Pearl Islands of the Gulf of Panama. Considering the faunal richness of the region as revealed by Carpenter, Adams, and Dall, the list is a small one, but several of the species now obtained were rare, and one, *Tellina barbaræ*, from the Pearl Islands, is new Six of the species are figured, by half tone process from photographs, on three plates, which are distinctly works of art

TRINIDAD WELL WATERS —It is seldom that a study of oilfield waters is of less significance, either in itself or in its bearings on exploitation problems, than the study of petroleum in any region, and Trinidad has shown itself to be no exception to this statement The technical data requisite to geochemical interpretations of the various waters encountered in oilfields here, have taken time to accumulate, although developments have been in progress for several years past, not until now has it been possible to present a co ordinated account of the hydrology of these oilfields as a basis of geological and economic considerations Messrs J S Parker and C A P Southwell's recent paper, read before the Institution of Petroleum Technologists, emphasises such considerations by showing that, as in most other cases, chemical investigations of associated waters with oil, lead to anticipation of water bearing strata likely to be penetrated by drilling wells, with such fore warning, casing programmes can be arranged accordingly and preparations for water shut off at specified depths be initially made, the data are also available, when correctly interpreted, as confirmatory evidence of subsurface structure, particularly when the strata involved are unfossiliferous, in the event of salt water invading a well or flooding an oil sand (through leaky casing or faulty seating), the source of such water may be determinable, while the discrimination between different waters (top, intermediate, bottom, edge), when possible, elucidates both extent and trend of oil reservoir rocks and of oil accumulation therein In short, the authors demonstrate that, now the essential chemical data are available to operators in Trinidad, solution of existing problems concerned with different waters in different fields should be possible, and future developments will have an advantage of the geochemical interpretations which their researches on the subject have made possible

TRUE BEARING AND DISTANCE DIAGRAM —A true bearing and distance diagram has been devised by Mr E A Reeves and published by the Royal Geographical Society (price 7s 6d) The diagram consists of the network of a hemisphere on the stereographic projection By its aid the true bearing of any point on the earth's surface from any other point can be easily found It also gives the distance between the two stations and allows the drawing of the arc of a great circle between them The diagram should prove of great value in survey expeditions obtaining wireless time signals in connexion with longitude determination Along with the diagram and pamphlet of instructions, there is given a spare unfolded copy on strong cartridge paper with a radial pointer

THERMIONIC VALVE POTENTIOMETER FOR E M F MEASUREMENTS —Most of the applications of thermionic valves to the determination of E M F measurements have the disadvantage that they depend upon the constancy of the valve characteristics and require constant sources of filament and plate potentials An apparatus described by H M Partridge in the *Journal*

of the American Chemical Society for January is claimed to be free from these limitations and may be used with cells of very high resistance, such as a cell containing two glass electrodes, since it is essentially electrostatic in operation A four electrode valve, together with a three electrode valve, is used, the second valve acting as an amplifier giving greater sensitivity No calibration of the valves is necessary, and the E M F is read directly from a voltmeter in the grid circuit of the first valve The accuracy depends largely on the degree of precision of the voltmeter

Molecular Hydrogen —Diatomic hydrogen (H_2), although regarded until recently as a simple substance has been shown by the new mechanics to be capable of existence in two modifications which have been termed ortho hydrogen and para hydrogen by analogy with corresponding helium atoms Considerable support for this idea has already been found in spectroscopic and thermal data, and in a recent issue of *Die Naturwissenschaften* (Mar 15) it has been reported independently by A Eucken, and by K F Bonhoeffer and P Harteck, that a separation of the components can be effected A Eucken has employed the simple device of holding hydrogen under pressure for some days, at liquid air temperatures changes in the relative amounts of the two forms present being followed by the increase in the rotational component of the specific heat of the gas In addition to this method, the other investigators appear to have made use of fractional condensation on charcoal at the temperature of liquid hydrogen, as well as direct liquefaction of the gas They claim to have prepared practically pure para hydrogen, and state that it is moderately stable if stored in glass vessels under normal conditions of temperature and pressure reverting only very slowly to the equilibrium mixture on standing, but that the change can be accelerated by an increase in pressure, and that it takes place rapidly under the influence of an electric discharge, or in the presence of platinised asbestos

A Portable Electric Harmonic Analyser — R Thornton Coe gave a demonstration at the Institution of Electrical Engineers on Mar 21 on an electric harmonic analyser for electric waves The operation of the instrument depends on the principle that a dynamometer instrument only gives a steady reading when the currents in the fixed and moving coils have the same frequency A small current of about the fifth of an ampere is obtained from the voltage or the current to be analysed, and passes through the moving coil of the instrument Through the fixed coil a current which follows accurately the sine law and the frequency of which can be varied is passed At the harmonic frequencies large deflections may be produced, and as the analysing current is read on a thermal ammeter the amplitude of the harmonic can be found The chief feature of the apparatus is the method of producing the analysing current by using a special contact disc driven by a small synchronous motor actuated from the alternating current circuit One ring of contacts is used for each harmonic A tuned circuit is used for improving the wave shape of the analysing current The instrument obtains each harmonic separately from steady readings on two instruments It is claimed that by its use alternating current waves can be analysed up to the forty ninth harmonic It is of importance in practice to determine the wave shapes produced by electric generators If an appreciable harmonic be present in the limits of audition, annoying interference with neighbouring telephone circuits may ensue This can generally be remedied by slightly modifying the generator circuits

Atomic Weight Reports —A correspondent points out that the German values for atomic weights given under the above heading in the issue of Nature for Mar 9, p 390 (in which the value for phosphorus should read 31 02, and not 31 62) are mainly identical with the values adopted in 1925 by the International Commission on the Chemical Elements in its atomic weight report which, though not an annual publication, was the successor to the former annual report of the International Committee on Atomic Weights It thus appears that the German Commission has retained the international values for the elements mentioned (*loc cit*), whilst the English sub committee has used F W Clarke s values

Distillation of Wood Tar in Hydrogen —Many years ago the interest of the Russian school of organic chemists in pyrogenic reactions was well known, and that this interest still continues has been shown by the work which has been published in recent years by W N Ipatiev from the Academy of Sciences in Leningrad The effect of heating organic substances under pressure in the presence of hydrogen and of alumina and iron catalysts has been investigated, and the results of this treatment on wood tar and tar oil are now described (*Berichte*, vol 62, p 401 February 1929) It is found that the use of hydrogen results in an increase in the yield of liquid products which are richer in hydrocarbons and low boiling fractions than the products of ordinary cracking Correspondingly there is a decrease in the proportion of unsaturated compounds formed, and this is reflected in the loss of the unpleasant smell which is a disadvantage of the ordinary product and in the absence of a tendency to darken on keeping The authors Ipatiev and Petrov, suggest that the new products might be used for extraction or lubricating purposes

The Nickel Chromium Plating Process Chromium is being extensively used instead of nickel as a protective coating for iron, not only for the purpose of producing a highly lustrous and durable surface, but also for the surface hardening of bearings That it has not yet displaced nickel is due to the difficulties encountered in electroplating In an article in the *Chemiker Zeitung* of Mar 13, Prof Pfanhauser director of the Langbein Pfanhauser Werke A G, Leipzig and Vienna, deals with these difficulties and describes how they have been overcome by a method which is protected by the patents of the Chrom Interessen Gemeinschaft By using a high current density, the time required to produce a stable and highly resistant coating of chromium has been reduced to five or ten minutes, the original iron or brass having previously received a layer of nickel 0 02 0 025 mm thick The advantages of using an intermediate layer of nickel are twofold, for not only is the cost of plating very greatly reduced, but also the risk of corrosion of the iron or brass by traces of chromic acid, deposited with the metal, is obviated The chief disadvantage has hitherto been the tendency for both metals to peel after a short time The reason for this is that some hydrogen is deposited with the metals at the cathode In order to overcome this defect, it is necessary in the first place to pay special attention to the deposition of the nickel, which must be sufficiently thick, and at the same time poor in hydrogen, to be able to absorb by diffusion the gas which is associated with the chromium layer Old fashioned nickel plating processes may be quite unsuitable for the purpose, and the solutions require very careful control A further source of trouble is due to traces of grease or oxide on the original metal, particularly on brass, which will ultimately cause blistering

Geological History of the Atlantic Ocean[1]

THE Atlantic is the best test case for the theory of the permanence of the ocean basins According to one view, the Atlantic trough is a primeval geographic feature and dates back to the pre Palæozoic According to an alternative view, it has been repeatedly so broken up by lands trending east to west across it that there has often been no sea entitled to the name of the Atlantic

The Icelandic Ridge, the northernmost of these cross lands, is generally accepted, and it was probably finally severed between the Upper Palæolithic and the Neolithic This land is shown by varied evidence from different geological periods to have extended as far south as a line from Newfoundland to Ireland or to the Azores It formed the northern shore of the Tethys

The main issue regarding the Atlantic relates to the southern side of the Tethys and the Brazilio Ethiopian land That the South Atlantic was occupied by land in the Palæozoic era is indicated by the absence of marine rocks from most of both coasts From Upper Carboniferous to Lower Jurassic times, Brazil and Africa were parts of Gondwanaland and a southern fauna and flora ranged through both The invasion of this land by the sea began in the Middle Cretaceous Period, with gulfs from the Mediterranean which reached Brazil and Angola they were closed to the south, as the marine fauna of Cape Colony is distinct and ranged westwards through Chile, and as the fresh water fauna was continuous between Africa and South America

This continuity is shown by the river fish porcupines, lizards, snakes and many invertebrates, of groups that were in existence in the Lower Kainozoic era The evidence shows that the connexion lasted until the end of the Oligocene, but it cannot have lasted much later, as the more specialised mammals and birds—for example, the humming birds—did not use it as a land bridge

The existence of this land connexion in Oligocene times is shown by the occurrence of the same shallow water marine animals in the West Indies and in the Mediterranean Some of them might have crossed by a chain of islands, but that the land was continuous is shown by the marine mollusca of the West Indies and the Mediterranean being distinct from those in the south The first commingling in South America was in the Upper Miocene (Entrerios Beds), according to H von Ihering A slight temporary land connexion was established in the Upper Miocene, as shown by the migration of *Hipparion gracile* to Europe and of African antelopes to the United States

This land connexion was severed too early to have served as Atlantis, though the Canaries may have been joined to the mainland up to the Pleistocene There is no geological evidence of any land connexion of Africa and South America in the time of man

The Atlantic is a relatively young geographical feature and due as held by Suess, to the growth of two gulfs, which projected northwards and southwards from the Tethys These gulfs were formed by subsidences which began in the Middle Cretaceous and have continued to the Pleistocene, and they finally united the Arctic, the North Atlantic (Poseidon), and the Nereus or the South Atlantic The Atlantic trough is the greatest of meridional geographical features, and is due to the collapse of a belt of the crust along faults and tensional fractures connected with the pressure of South America westward against the Andes

[1] From the presidential address to the Geological Society of London delivered by Prof J W Gregory F R S on Feb 15

Cylinders for the Storage and Transport of Gases[1]

THE publication of the third and fourth reports of the Gas Cylinders Research Committee of the Department of Scientific and Industrial Research completes the work of that Committee The first report dealt with ordinary commercial cylinders for permanent gases, the second with the periodical heat treatment of carbon steel cylinders, and recommended that such cylinders should be made of 0 45 per cent carbon steel as an alternative to the 0 25 per cent carbon steel approved in 1895, whereby the working stress in the cylinders would be raised from 8 to 10 tons per square inch, while the weight would be reduced by about 20 per cent The first report (see NATURE, 109, 460, 1922) is now out of print, but a revised summary of the recommendations it contained has been issued lately

A further reduction of weight to one third of that recommended by the 1895 Committee is possible by the use of alloy steels This is called for in the case of cylinders used for medical, aeronautical, and mine rescue work, and the question of constructing cylinders of duralumin and alloy steels containing nickel, chromium, and molybdenum has been examined by the Committee The third report gives details of this investigation Commercial and mechanical difficulties rather restricted the scope of the work, and alloy steel cylinders alone have been investigated properly The Committee recommends the use of nickel chromium molybdenum steel cylinders for the storage and transport of 'permanent gases, the steel to have the following composition Nickel, 2 5 per cent chromium, 0 6 per cent, molybdenum, 0 6 per cent manganese 0 6 per cent, carbon, 0 3 per cent silicon 0 15 per cent, sulphur, 0 4 per cent (max) and phosphorous, 0 03 per cent (max), and the remainder iron and to have the following mechanical properties Ultimate tensile strength, 55 65 tons per square inch yield stress, not less than 45 tons per square inch an elongation not less than 18 per cent on 2 inch gauge length Seamless and weldless finished cylinders of about 20 cubic feet of gas capacity are required to be subjected to a hydraulic proof pressure of 2700 lb per square inch, to stand a pressure of 2550 lb per square inch and show no sign of leak, and to withstand the impact of an armour piercing bullet (Mark vii P) without bursting when filled with air at a pressure of 1800 lb per square inch The thickness of the cylinder wall for cylinders of 4 inch outside diameter must not be less than 0 080 inch, and particles of shale, oil, grit, filings, etc, must be carefully removed from the cylinder They are to be subjected to the hydraulic test at least once in every two years

The considerations that are of importance in the case of cylinders used for the storage and transport of *liquefiable* gases are radically different from those ruling in the case of permanent gases In the former case, so long as the cylinder is not *completely* filled with liquefied gas, the internal pressure is the saturation pressure, and this in general is quite low and

[1] Department of Scientific and Industrial Research Ordinary Commercial Cylinders for the Permanent Gases. Summary of Recommendations (Revised) Pp iii+7 4*d*. net. Third Report of the Gas Cylinders Research Committee (Alloy Steel Light Cylinders) Pp iii+74+13 plates 2*s* 6*d*. net Fourth Report of the Gas Cylinders Research Committee (Cylinders for Liquefiable Gases) Pp v+151 4*s* net (London H M Stationery Office 1929)

increases *relatively* considerably, but *absolutely* only slightly with rise of temperature Liquefied gas, however, has a relatively high coefficient of thermal expansion, and unless a sufficient free space is left in filling a cylinder, dangerous pressures may be developed owing to the cylinder becoming filled with liquefied gas on rise of temperature Cylinders for the permanent gases are designed on the basis that the stresses in a cylinder wall due to internal pressure are limited say, to one quarter of the ultimate strength of the material The same basis, applied to cylinders for liquefiable gases, would result in the production of cylinders altogether too fragile for commercial purposes

These considerations and others are set out in detail in the very interesting fourth report of the Committee The storage and transport of liquefied sulphur dioxide, ammonia, chlorine, methyl and ethyl chlorides, hydrocyanic acid, phosgene, carbon dioxide, nitrous oxide, and ethylene are considered Acetylene was excluded from the Committee s terms of reference It is recommended that cylinders for the transport of these gases should be made of seamless tubes of carbon steel produced by the acid or basic open hearth process and having the following approximate composition Carbon, 0 20–0 25 per cent sulphur, not exceeding 0 045 per cent phosphorus not exceeding 0 045 per cent manganese 0 45 0 75 per cent silicon not exceeding 0 2 per cent, and the rest iron Alloy steel is not to be used The thickness of the cylinder wall is to be dependent upon the maximum internal pressure and the external diameter of the cylinder, and formulæ for deducing such thickness are given in the report After manufacture, cylinders are to be heated uniformly at 860° 890° C and allowed to cool in still air

Filling ratios for various pressures in temperate and tropical climates for each of the gases are tabulated Finished cylinders are to be subjected to specified tensile and hydraulic stretch and flattening tests and are to be provided, as in the case of cylinders for containing ‘permanent’ poisonous or inflammable gases, with completely protected valves which must be left handed in the case of cylinders containing inflammable gases Hydrocyanic acid must not be stored for more than 8 months its purity must be at least 98 per cent and it should be stabilised to prevent polymerisation The valves of cylinders for storing carbon dioxide may be fitted with a safety device, for example a copper or vulcanite disc forming a gas tight joint with the valve seat

The reports contain valuable appendices relating to tests of cylinders the determination of some of the physical properties of commercial samples of sulphur dioxide, ammonia chlorine methyl chloride, carbon dioxide, nitrous oxide ethylene hydrocyanic acid, and ethyl chloride

Vertebrate Fossils from Glacial and Later Deposits in Scotland [1]

THE work referred to below is an important contribution to our knowledge of the vertebrate fossils from the glacial and associated post glacial beds of Scotland in the Hunterian Museum, University of Glasgow This monograph was planned twenty years ago Various causes have contributed to the delay in publishing but Prof Gregory and Dr Ethel Currie are to be congratulated on finally bringing the work to conclusion

Several eminent specialists have collaborated in examining and naming different parts of the collection The resulting publication however, is more than a catalogue of fossils Detailed and critical descriptions of specimens are first of all given, all the more important examples being figured either in the text or on plates There follows a series of notes on the localities and geological horizons of the different occurrences In one or two instances the views expressed herein are matters of controversy, but the authors have been careful to direct attention to other opinions It may be noted, for example, that Prof Gregory s belief in the marine origin of Boulder Clay is not generally accepted in Scotland In addition the interpretation of the evidence as to the exact position of the Cowdon Glen deposits is at variance with that of some other eminent Scottish geologists It appears in this connexion that Craig s description of the glacial sequence in this locality has been slightly misread Prof Gregory classes the deposits as Neolithic, but the alternative reading would make them older

The next section of the monograph contains a table showing the distribution in time of the characteristic Scottish mammal remains, with a proposed correlation with the Thames Valley sequence No Scottish mammals earlier than Lower Mousterian are known Deposits of this age in Scotland are correlated in time with the Late Middle Terrace of the Thames Valley, and the period of maximum glaciation in both Scotland and England It must be noted, however, as the authors point out, that vertebrate fossils in the glacial and later deposits have been found in very few localities in Scotland, and consist only of isolated fragments Nothing occurs corresponding to the rich Pleistocene vertebrate faunas of south east England

The monograph concludes with a comprehensive bibliography We agree with the authors in hoping that its publication will stimulate interest, and result in further chance discoveries being carefully recorded and the specimens placed in suitable keeping

[1] Monographs of the Geological Department of the Hunterian Museum, Glasgow University 2 The Vertebrate Fossils from the Glacial and Associated Post-Glacial Beds of Scotland in the Hunterian Museum University of Glasgow, and their Evidence on the Classification of the Scottish Glacial Deposits By Prof J W Gregory and Dr Ethel D Currie Pp vi+26+3 plates (Glasgow Jackson Wylie and Co, London Simpkin Marshall Ltd 1928) 7s 6d net.

H M Dockyard Schools and Naval Architecture

MR A W JOHNS concludes a series of six articles in *Engineering* for Mar 29, on "The Dockyard Schools and the Second School of Naval Architecture," a series which fills in a gap in the history of the Admiralty system of training shipwrights and naval architects Though all Boards of Admiralty have not been possessed with equal zeal in such matters, generally speaking the Admiralty has been a pioneer in technical education Mr Johns' articles necessarily present but one aspect of their activities, which to day range from the training of bandsmen to courses of strategy for captains and admirals Only so recently as September 1925, Sir W J Berry and Engineer Vice Admiral Sir Robert Dixon gave an account of the Admiralty system of higher education for naval constructors and engineers officers to the British Association, and they stated that it is no exaggeration to say that during the last half century nearly all advances in warship design have been originated by officers who have passed through the training at Kensington or Greenwich

Not only have Admiralty students been responsible for advances in warship design, but also many of them have become associated with great shipbuilding firms,

with Lloyds' Register, and with foreign navies, while nearly all the occupants of the various chairs of naval architecture in Great Britain have been held by men whose professional training began in H M Dockyards or at one of the schools maintained by the Admiralty

The dockyard schools at Portsmouth, Devonport, Chatham, and elsewhere for the education of apprentices, have a continuous history from 1843, and Mr Johns says they "may be placed amongst the most efficient technical institutions in the country" In the first years of their existence they were inspected six times by Canon Moseley, the mathematician, and to his suggestions may be traced many of the improvements afterwards made The Schools of Naval Architecture were separate institutions, the first (1811–1832) and the second (1848–1853) being at Portsmouth, the third (1864–1873) at South Kensington, the fourth and still existing one being founded at Greenwich Royal Naval College in 1873 Of the first, Mr Johns gave an account in *Engineering* in 1926, the third was the subject of an article by Sir William Smith in the same journal in July 1923, and Mr E L Attwood read a paper to the Institution of Naval Architects in 1905 on the work at Greenwich Sir William White also referred to the work done at South Kensington and Greenwich in a paper read at the jubilee meeting of the same body in 1911

Mr Johns in his articles gives an interesting account of the development of the dockyard schools and of the Second School of Naval Architecture, otherwise known as the Central Mathematical School, and recalls some of the important work done by the professors, masters, and pupils, such as Dr Woolley, Rawson, Sir Edward Reed, and Sir Nathaniel Barnaby, the last two of whom held the responsible post of Chief Constructor of the Navy A review of the progress of the various schools and of the careers of those who have passed through them bears eloquent testimony to what can be accomplished by a government department desirous of encouraging talent and industry and of obtaining for itself and the nation at large, workmen and officers with a high standard of professional and technical knowledge

Studies on the Polysaccharides

At a meeting of the London Section of the Society of Chemical Industry on Mar 4, Prof A R Ling, director of the British School of Malting and Brewing, University of Birmingham, described results of recent researches into the structure of starch and glycogen, conducted by himself and his collaborators

In addition to amylose and amylopectin, the two main constituents of the starch of potatoes, arrow root, etc, the granules obtained from cereals contain a third substance, amylohemicellulose Amylose and amylopectin are hexa amyloses partially esterified as calcium phosphate esters, whilst amylohemicellulose is a silicic ester of amylose Hydrolysis of starch paste with barley diastase converts amylose quantitatively into maltose, whereas amylopectin yields soluble $\alpha\beta$ hexa amylose, which is resolved in turn by malt diastase to various glucose derivatives Amongst these are found glucosido maltose and isomaltose Recent study of enzyme action upon these two products has revealed the fact that both possess α linkages, and not β linkages as was hitherto supposed

Prof Ling has also produced evidence to show that if glycogen, a polysaccharide widely disseminated through the animal kingdom and found also in fungi and in yeast, is not identical with amylopectin, as suggested by Pringsheim, the two compounds are certainly very similar Samples of glycogen after hydrolysis by malt diastase gave products which could be investigated with the help of the osazone reaction Two compounds were isolated, namely, a disaccharide and a non reducing sugar The former agrees in physical properties with isomaltose and possesses a γ (1 4) ring It seems probable that all the oxide rings in glycogen and amylopectin are of this type and that the conversion of glycogen into lactic acid in the muscles during contraction is best explained by assuming that the glucose involved possesses the γ structure

The lecture was followed by an account by Dr F W Norris, of Prof Ling's department, of recent researches on pectin, an important constituent of fruit jellies After reviewing earlier work on the subject, Dr Norris referred to Ehrlich's resolution of pectic acid into arabinose, galactose, and tetragalacturonic acid In 1925, Nanji, Paton, and Ling proved that these substances are linked in the proportion of 1 1 4 as anhydrides in a ring structure, the acid carboxyl groups being free An attempt to remove the acid groups, in order to produce a hemicellulose, gave an unexpected result, the product actually obtained being pure galactose galacturonic acid The adoption of the ring or hexagon formula helped to throw some light upon the interpretation of analyses of methoxyl groups, and it seems probable now that the predominating unit in soluble pectin is trimethylpectic acid, which is present in fresh orange juice Reference was made to recent work by Candlin and Schryver, who obtained a hemicellulose by the action of alkali on pectic acid Schryver has suggested a new class name—the polyuronides—for all these compounds

A wide and interesting field of research has been opened up and much remains to be done to clear up many existing perplexities

University and Educational Intelligence

London —The annual dinner of the fellows of University College will be held at the College on Tuesday, April 30, in commemoration of the laying of the first stone of the College buildings by H R H the Duke of Sussex on April 30, 1827 Prof F W Oliver, Quain professor of botany in the University, who was elected a fellow of the College so long ago as 1886, will preside

The following courses of free public lectures are announced at Bedford College for Women, at 5 15 on April 29 and May 1, "Abolishing the Arctic," and "The Northward Course of Empire," by Dr V Stefansson, at University College, at 5 30 on April 29, May 7 and 13, "Geometry a Brief Review," by Prof H F Baker, at University College, at 5 15 on April 29 and 30 and May 1, "Drug like Actions of Some Food Constituents," by Prof E Mellanby, at University College, at 5 on May 2, 9, 16, 23, and 30, and June 6, "Special Sense Physiology," by R J Lythgoe, at St Thomas's Hospital, at 5 on May 2, 9, 16, 23, and 30, and June 6, "Dietetics," by Prof S J Cowell, at University College, at 4 on May 3 and 10, "Some of the Sequels of Epidemic Encephalitis (Lethargica)," by Prof A J Hall

Applications for agricultural scholarships and agricultural and veterinary research scholarships are invited by the Ministry of Agriculture and Fisheries Form A 472/T G for the former and form 900/T G. for the latter may be obtained from the Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S W 1 The completed forms have to be returned by June 15

Calendar of Patent Records

April 22, 1823—The first patent for a roller skate was the English one granted to Robert John Tyers, fruiterer of Piccadilly, on April 22, 1823 The skate had a single line of wheels or rollers, which either were of graduated diameter or were so fitted that their lower edges lay on the line of a circle

April 23, 1784—The well known cabinet lock of Joseph Bramah—the first of the revolving barrel type—was patented on April 23, 1784, and remains unaltered to the present day It was one of the first to give real security against being opened by a false key, but that it, like most locks, could be picked by an expert was proved when the American A C Hobbs took up Messrs Bramah's challenge in 1851 and succeeded in opening the lock, though only after 53 hours' work

April 23, 1793—Sir Samuel Bentham—a brother of Jeremy—is one of the most noted of English inventors His many inventions, not all of which were patented, cover a wide field, but most of his important work was done in connexion with the naval dockyards, where he introduced reforms not only in the methods of shipbuilding but also in office and workshop administration and practice His most famous patent is No 1951, dated April 23, 1793, the specification of which is a valuable treatise on the application of machinery to the working of wood and metal

April 23, 1884—April 23, 1884, is the date of Sir Charles Parsons' patents for the steam turbine The engine was first used for driving dynamos in electricity works, where within a few years its use decreased the coal consumption by one half The first application to steamships was in the *Turbinia*, which was built in 1894 and attained a speed of more than 32 knots The engine of the *Turbinia* is now in the Science Museum

April 25, 1793—On April 25, 1793, there was granted to Captain Joseph Huddart a patent for his new method of making rope cable, in which all the yarns are disposed in concentric cylindrical layers about a centre yarn, an arrangement designed to give a more equable distribution of strain upon the yarn

April 25, 1863—Linoleum—both the material and the word—was the invention of Frederick Walton, who made his first application for a patent for the new floor cloth on April 25, 1863 There has been little change in the process of manufacture since its first commercial production at Staines

April 26, 1814—The sewing machine did not become commercially successful until Elias Howe's United States patent of 1846, but there were several prior inventors who can claim consideration One of these is Josef Madersperger, of Vienna, who applied to the Emperor Francis I for an Austrian patent for a sewing machine on April 26, 1814 A patent for six years was granted to him early in the following year, but the machine was never put into practical use Madersperger's original model was shown at a meeting of the Nied Österreichischer Gewerbe Verein in 1840 and secured for the inventor the society's medal, but in spite of this recognition Madersperger died in extreme poverty The model is now in the Technical Museum at Vienna

April 27, 1879—Electricity was first used for lighting railway carriages by the London, Brighton, and South Coast Railway, which in 1881 fitted up a Pullman car with an accumulator installation A system employing a belt driven dynamo on one of the carriages for supplying current to Geissler tubes throughout the train had, however, been patented in Germany by E Hinkefuss and Gustav Wesel, engineers of Breslau, on April 27, 1879

Societies and Academies

London

Geological Society, Mar 20 **Sir Douglas Mawson** Some South Australian algal limestones in process of formation A record of three different types of limestone, now actually in process of formation under the influence of plant growth, occurring in the south eastern region of South Australia In each of the localities examined, whether inundated in winter only or permanently inundated, the formation of limestone is being determined by blue green algæ—**Arthur W Groves** The unroofing of the Dartmoor granite, and an outline of the distribution of its detritus in the sediments of southern England A systematic outline mineralogical survey has been made of the sediments of southern England, from the base of the Permian in Devon (Watcombe Clay) up to the Lenham Beds of the North Downs The minor intrusions above the granite were being rapidly eroded in Permo Triassic times, but there is no evidence of the actual granite being exposed at that period No proof has been obtained of direct derivation of detritus from the Dartmoor granite in the Jurassic rocks The earliest evidence of the exposure of the granite is in late Wealden times Throughout Upper Cretaceous times—particularly during the Selbornian epoch—the Dartmoor granite contributed enormous quantities of detritus to the sediments of southern England, reaching as far afield as Kent and Oxfordshire, and perhaps farther The Cornish Pliocene was largely derived from the Cornish granites The St Keverne outlier is mainly derived from the Falmouth and Bodmin masses, and yields no evidence of Dartmoor detritus A number of new occurrences of dumortierite are recorded

Society of Public Analysts, April 3—**L H Lampitt, E B Hughes**, and **H S Rooke** Furfural and diastase in heated honey Modifications of Fiehe's test and the aniline acetate test for furfural have been devised If honey gives pronounced reactions with both of these tests it is probably adulterated, unless there is evidence that it has been strongly heated Such honey has usually been found to be caramelised and unfit for use Honey contains two diastatic enzymes, for it reacts with starch, yielding both dextrins and reducing sugars If it is heated above 85° C its diastatic activity is very rapidly destroyed—**J W Haigh Johnson** Further notes on methods of sewage and water analysis, anti oxidation and stabilisation of pollution Comparative results on river waters have shown that the Graph Standard method is much to be preferred to the Royal Commission's test Three main types of biological oxidation curves are recognisable for polluted liquids (1) Unstable type, characterised by very rapid, fairly uniform absorption of not more than five days' duration, followed by (2) semi stable type, having greatly diminished but very uniform oxidation rate, of indefinite duration, until (3) nitrification supervenes From one third to two thirds of the chemically determined organic matter is recovered from sewage during purification without any appreciable absorption of oxygen The effect of oxygen is apparently to oxidise unstable substances, whilst semi stable substances are stabilised and precipitated as a relatively non oxygen absorbing mud of increasing stability—**B J F Dorrington** and **A M Ward** Potassium cyanate as a reagent for the detection of cobalt Potassium cyanate reacts with cobalt to form a blue complex The test, which is most sensitive when the reagent is used in alcoholic solution, will detect cobalt in a one hundredth molar solution of cobalt nitrate

EDINBURGH

Royal Society, Mar 4 —**Hans Przibram** Quanta in biology The movements of cold blooded animals follow van 't Hoff's law, so also do many other processes of the living organism It is suggested that the dissociation of ultimate particles to which the characteristics of life are attached is responsible for the exhibition of this phenomenon A statistical conception which accounts for the decrease of the temperature coefficient with the raising of the temperature is developed Przibram's work on the discontinuous growth of the Mantidæ and the conclusions of Koltzoff and Heidenham lead to an attempt to introduce a more systematic notion of fundamental quanta in biology

PARIS

Academy of Sciences, Mar 11 —**R Bourgeois** Concerning the programme of the expedition organised by the Bureau des Longitudes for the observation of the total eclipse of the sun of May 9, 1929 The station chosen for the observatory is the island of Bai Kan an outline of the scheme of observations proposed is detailed —Jules Richard was elected *correspondant* for the Section of Geography and Navigation in the place of the late Roald Amundsen —**Jacob** Addition to the note "The application of the generalised integrals of Fourier to the calculus of probabilities" **A Th Masloff** An application of the theorem of Eisenhart —**Bertrand Gambier** Imaginary deformations of real surfaces cyclic systems —**Marcel Vasseur** The relations between the two focal sheets of a rectilinear congruence —**C Popovici** Functional equations and their parallelism with differential equations —**Georges Giraud** The solubility of the generalised problem of Dirichlet —**Georges Calugaréano** The calculation of the M exceptional values of integral functions of finite order —**Victor Vâlcovici** Generalisation of the theorem of Kœnig —**Benjamin Jekhowsky** Calculation concerning the positions of the minor planets —**L d'Azambuja** The structure of the solar chromosphere —**L Driencourt** The choice of the projection to be adopted for aerial navigation maps —**Vasilesco Karpen** Demonstration of the relations of Maxwell Clausius and of Clapyron —**S Piña de Rubies** The arc spectrum of samarium Measurements made at the normal pressure between 3100 A and 2750 A —**Jean Savard** The ultra violet absorption spectra of the ortho, meta, and para cresols —**G Jausseran** The evolution of the latent image The relations between the density of the image and the time elapsed between the exposure and the development are shown graphically The effects of the evolution of the latent image are considerable and must be taken into account in the photographic comparison of two non simultaneous luminous intensities —**G Athanasiu** The inversion of the photo voltaic effect by the OH and H ions —**Eugène Cornec and Henri Krombach** The ternary system water, sodium nitrate, potassium nitrate This system has been studied through a wide range of temperatures a general outline of the results is given —**Horacio Damianovitch** The action of helium upon platinum The product obtained by the action of helium upon platinum under the influence of a moderate electric discharge at low pressures presents properties clearly distinct from those of the metal itself, and it retains helium in a fairly stable form —**Ed Bayle and L Amy** The estimation of the hydrofluosilicic anion and that of fluorine in general —**Marcel Godchot and Mlle Cauquil** The methylation of cycloheptanone This ketone, treated with sodium amide and methyl iodide, gives rise to α, α dimethyl cycloheptanone and an α methylcycloheptanone, the first being formed in relatively small quantity —**M Battegay, H Buser, and E Schlager** A crystallised acetin and diglycide **R Cornubert and Ch Borrel** Contribution to the study of the ketonic function —**Mlle E Jérémine and P Fallot** The presence of a variety of jumillite in the neighbourhood of Calasparra (Province of Murcia) **Alberto Betim** The theory of Wegener in the light of some geological observations concerning Brazil —**G Baeckeroot** The extension of the *Pierre de Stonne* in the Grand Duchy of Luxemburg —**Albert Michel Lévy** The existence of a level characterised by touchstones with Radiolaria at the base of the marine Carboniferous, in le Morvan —**M Couvreur** The general structure of the shells of gastropods —**C E Brazier** Actinometric data for the region of Paris from measurements made at the Observatory of Parc Saint Maur The average quantity of heat received in one year by one square centimetre of the earth's surface in the climate of Paris is 93 large calories —**Marcel Mascré** New remarks on the fixation of the chondriome of the plant cell —**Guilliermond** New observations on the vital coloration by neutral red in plant cells —**Georges Montandon** An ape of anthropoid appearance in South America —**Ph Joyet-Lavergne** The relations between metabolism and cytoplasmic sexualisation —**Raymond-Hamet** Tropine and atropine —**René Hazard and Michel Polonovski** The rôle of the tertiary amine function in the dipiperidine nucleus —**Raymond Poisson** *Paracoreomyces Thaxteri*, a parasite of *Stenocorixa protrusa* —**F Diénert and P Etrillard** The sterilisation of water by chlorine The experiments described are opposed to the view that the sterilisation of contaminated water is due to an abiotic radiation, but are in agreement with the older hypothesis of direct action of the chlorine on the micro organism

GENEVA

Society of Physics and Natural History, Feb 7 —**Ed Parejas** Geological observations in Corsica (1) The Razzo Bianco near Venaco The alpine dynamic metamorphism has determined in the limestone elements of the base of the nummulitic conglomerates of Venaco a fibrous texture of the calcite, and this is again met with in the limestones of Razzo Bianco The latter must therefore have been marmorised during the Tertiary Alpine paroxysm A later and weaker thrust has carried the Razzo Bianco limestones on to the granite —**R Wavre** A new method in geodesy The author shows that, starting with a method that he has given in his earlier communications, some important classical results of higher geodesy can be co ordinated and new results obtained This method consists essentially in employing a development in a convergent series where Laplace and Poincaré made use of a divergent development Hence the method conforms to the desideratum formulated by Tisserand The exact formula for the flattening is also given by M Wavre —**W Schopfer** Theoretical remarks on the question of the metabolism of the sexes The author examines the old theory of the metabolism of the sexes (♀ anabolism and ♂ catabolism), he shows that if, when expressed too rigidly, it appears inexact, nevertheless modern researches give it some experimental support The sexual metabolic differences occur even in the Mucorineæ, where the morphological differentiation of the sexes is scarcely noticeable

VIENNA

Diary of Societies

FRIDAY April 19

Physical Society (at Imperial College of Science) at 5 —Presentation of the Guthrie Medal to Dr C E Guillaume —Prof W R Bridgman The Properties of the Elements under High Pressures (Guthrie Lecture)

British Institute of Radiology (Medical) at 5 —Informal Discussion on Bone Diseases (especially Multiple Myeloma).

Institution of Mechanical Engineers, at 6 —W Reavell The Standardisation of Keys and Keyways

Institution of Electrical Engineers (London Students Section) (Annual General Meeting), at 6 15 —V E Connor The Manufacturing and Testing of Submarine Cables

Royal Photographic Society of Great Britain at 7 —B Chambers and F W Sharp Carbon and Carbro

Society of Dyers and Colourists (Glasgow Section) (at 7 Gordon Street, Glasgow) at 7 15 —Annual General Meeting

West Bromwich Engineering Society (at Kenrick Technical College West Bromwich) at 7 30 —D G Mackintosh The Erection of Steel Bridges

Junior Institution of Engineers at 7 30 —Lt Col J T C Moore Brabazon Early Aviation (Lecture).

Institute of British Foundrymen (Sheffield Branch) (Annual Meeting) (at Albany Hotel Sheffield) at 7 45 —Recent Developments in Cupola Control

Royal Society of Medicine (Electro Therapeutics Section) at 8 30 —Dr S G Scott Myeloma—Differential Diagnosis —Dr J D White Bone Lesions in Tropical Diseases

Royal Institution of Great Britain, at 9 —Prof Owen T Jones History of the Grand Canyon Yellowstone National Park

Society of Dyers and Colourists (Manchester Section) (at Manchester). —Annual General Meeting

SATURDAY April 20

Institution of Municipal and County Engineers (Southern District) (at Council House Bristol) at 10 30 a m —H F Proctor Description of the New Power Station Portishead

North of England Institute of Mining and Mechanical Engineers (Newcastle upon Tyne) at 2 30 —C H Leeds Boring against Workings likely to contain an Accumulation of Water or other Liquid Matter and a Method of Negotiating a Fault —C N Kemp The X Ray Analysis of Coal the Radiographic Variables and their Control —Papers open for discussion —Roof Control on Longwall Faces J F C Friend Diamond Boring Applied to Tapping Drowned Areas Underground F F Smyth Land Drainage H C Pawson The Laws of Motion of Particles in a Fluid R. G Lunnon

Mining Institute of Scotland (at Royal Technical College Glasgow).—Annual Meeting

MONDAY April 22

Royal Geographical Society (at Lowther Lodge), at 4 —Miss E R G Taylor Roger Barlow an Early XVIth Century Geographer

Victoria Institute at 4 30 —Dr A. T Schofield Humanity

Institution of Mechanical Engineers (Graduates Section London), at 6.30 —Informal Discussion on The Engineer as a Salesman

Institution of Automobile Engineers (Graduates Meeting) (at Loughborough College), at 7 —H M Smith Steering Gears

Institution of Automobile Engineers (North of England Centre) (at Sheffield University) at 7 —Dr H J Gough Recent Developments in the Study of the Fatigue of Metals

Royal Photographic Society of Great Britain (Informal Meeting of Kinematograph Group) at 7 —H A Carter The De Vry 16 mm Synchronised Sound Motion Picture Apparatus with Projection of Films and Synchronised Gramophone Records.

Royal Institute of British Architects at 8 —J Begg The Work of George Wittet

Royal Society of Arts, at 8 —Sir E Denison Ross Nomadic Movements in Asia (Cantor Lectures) (II).

Royal Society of Medicine (Odontology Section), at 8 —G Northcroft The Migration of a Foreign Body —S Friel The Relation of Function to the Size and Form of the Jaws.

Royal Geographical Society (at Polytechnic, Regent Street), at 8 30 —G M Dyott The Search for Col Fawcett (with Kinematograph Films)

TUESDAY, April 23

Royal Society of Medicine (Medicine Section), at 5 —Dr O Leyton How can we decide whether a case of Glycosuria should be treated?—Dr W T Munro Pulmonary Tuberculosis due to Bovine Tubercle Bacilli

Zoological Society of London at 5.30 —Secretary (a) Report on the Additions to the Society's Menagerie during the month of March 1929 (b) Exhibition and Note on the Society's Scientific Publications.—S G M Ramanujam The Study of the Development of the Vertebral Column in Teleosts as shown in the Life history of the Herring —Prof E B Poulton British Insectivorous Bats and their Prey

Institution of Civil Engineers at 6.

London Natural History Society (at Winchester House E C) (Bacot Memorial Meeting) at 6 30 —R S Bagnall Plants and their Insect Associates

Royal Photographic Society of Great Britain at 7 —H R Ward Some Continental Zoos

Institution of Automobile Engineers (Wolverhampton Centre) (at Engineering and Scientific Club Wolverhampton), at 7 30 —H W Pitt Central Lubrication of Chassis Bearings

WEDNESDAY April 24

Eugenics Society (at Royal Society) at 5 15 —C J Bond Bilateral Asymmetry in Animals and Man and its Relation to Cross breeding (Lecture)

Newcomen Society for the Study of the History of Engineering and Technology (at Caxton Hall), at 5 30 —C F Dendy Marshall The Rainhill Locomotive Trials of 1829

Geological Society of London at 5 30 —R. Murray Hughes The Geology of Part of North Western Rhodesia with Petrographical Notes by A A Fitch

Royal Society of Arts, at 8 —Lynton Fletcher Recent Developments in Educational Broadcasting

THURSDAY April 25

London Mathematical Society (at Royal Astronomical Society) at 5 —S D Chowla Some Formulae Connected with Gauss's Sums —Doris M Hirst On Expansions which are Formally Reduced to Zero by the Operator Sinh $D-cD$ —Prof E W Hobson On a Generalisation of Watson's Expressions for Legendre's Functions —Prof R. L Jeffery The Continuity of a Function Defined by a Definite Integral —J Tennant Nasik or Pandiagonal Squares of the Order of any Odd Prime

Institute of Pathology and Research (St. Mary's Hospital W 2) at 5 —Sir Almroth E Wright The Experimental Method in Medicine

Chemical Society (at Institution of Mechanical Engineers) at 5 30 —Sir Harold Hartley Theodore W Richards Memorial Lecture.

Royal Society of Medicine (Urology Section), at 5 30 —Dr P J Cammidge Prostatectomy in Diabetics

Institution of Electrical Engineers, at 6 —Dr G C Simpson Lightning (Kelvin Lecture)

Royal Aeronautical Society (at Royal Society of Arts), at 6 30 —Squadron Leader C L Scott By Flying Boat to India.

FRIDAY, April 26

Physical Society (at Imperial College of Science), at 5 —T Smith Dr C F C Searle Instructor Capt T Y Baker Dr J W French W E Williams O G Vernon H H Emsley C W Hansel H Tunley J Moore Conrad Beck, V T Saunders and Dr C V Drysdale Discussion on The Teaching of Geometrical Optics

Royal Society of Medicine (Disease in Children Section) at 5

Royal Institution of Great Britain at 7 —E A Salt Platinotype

Institution of Electrical Engineers (Scottish Centre) (at University College Dundee) at 7 30 —W Holmes Load levelling Relays and their Application in connexion with Future Metering Problems

Royal Society of Medicine (Epidemiology Section) at 8 —Dr J G Thomson Endemic Malaria in Southern Rhodesia.

British Psychological Society (Industrial Section) (at National Institute of Industrial Psychology), at 8 —J N Langdon Evidence of a Central Factor in Tests of Manual Dexterity

Royal Institution of Great Britain at 9 —Prof R. W Chambers English Civilisation from Alfred to Harold 900–1066

PUBLIC LECTURES

MONDAY April 22

The University Glasgow at 5 —Sir Norman Walker Medical Education and Qualification in the United States

TUESDAY April 23

Gresham College (Basinghall Street) at 6 —A. R. Hinks Latitudes and Longitudes (Gresham Lectures). (Succeeding Lectures on April 24 25, and 26)

Institution of Mechanical Engineers, at 8 —C E Stromeyer What Health and Civilisation owe to Engineering (Chadwick Lecture)

WEDNESDAY, April 24

University of Birmingham at 4.30 —Dr C Singer Epochs of Medical History (Succeeding Lectures on May 1 and 8, June 19 and 26)

Mansion House (arranged by British Science Guild), at 4.30.—Developments of British Chemical Manufactures. Lord Melchett in the chair —Sir Frederick Keeble Fertilisers from the Air —A B. Shearer Rayon (Artificial Silk) —F H Carr Synthetic Drugs

FRIDAY, April 26.

World Association for Adult Education (16 Russell Square, W C 1), at 8 30 —Miss R M Fleming Soil and Civilisation in Russia.

SATURDAY, APRIL 27, 1929

No 3104, Vol 123]

The Smithsonian Institution and Scientific Education

SINCE the last Report of the Smithsonian Institution was published, a new secretary, Dr Charles G Abbot, Director of the Astrophysical Observatory, has been appointed, and the Report to June 30, 1928, appears over his signature It is impossible in these columns to mention, far less to do justice to, the manifold activities of this wonder ful institution, with its great museums of science and of art, its zoological park, its astronomical observatory and its international exchange service But the new secretary, in virtue of his appoint ment has felt it to be his duty to make a wide survey of the activities of the Smithsonian," in order to gain some knowledge of the most effective ways in which it may advance the mission of its founder, James Smithson, for the increase and diffusion of knowledge amongst men '

Dr Abbot s conclusions are of great interest, and since they are of general application, deserve wide attention He points out that, to the casual observer, it may appear that the most important function of the Smithsonian is the administration of the national museum, art galleries, and zoological park confided to its direction The educational value of these is great, but a closer analysis would show that their influence is largely confined to the neighbouring States, and that a lessening of influence, which increases rapidly with distance, affects more distant States and foreign countries

On the other hand, to be contrasted with this relatively local influence, is the wider reach of the International Exchange Service, as associated with the publications of the Institution Reviewing the whole field, Dr Abbot is led to the conclusion that the care of the public exhibits, educational and interesting though they are, is after all not the greatest duty of the Smithsonian Institution In his view its main services to science are

In the collection of new specimens, which the passage of a few more years might prevent for ever , in the study of existing national collections to unlock the treasures of knowledge which they certainly contain , in the promotion of researches growing out of our expert experience in the field of radiation , in the publication of knowledge in both technical and popular forms , and in the wide diffusion of knowledge through exchanges and correspondence in all these lines, activities entirely suited to the genius and situation of the Smith sonian, which in their world wide application and future promise, outrank in value the more local influence of the public exhibitions "

The one thing that is lacking to promote these

researches on the scale they deserve is, the impecunious institutes of Britain will learn with a shock of sympathy, lack of adequate means

Put broadly, Dr Abbot's view rather sounds like pitting against one another the advance of technical knowledge and the scientific education of the people, the latter of which is bound in the end to be more local in its development, since the less educated a person may be the more he must depend on sense impressions and the less on the mental stimulus of the written word, and the Smithsonian plumps heavily for the former Now we are not convinced that the contrast is a necessary one, since if both the scientific education of the people and the advance of technical scientific knowledge are essential, it can scarcely be said that one is of more value than the other Both are necessary ingredients in the sum of scientific advancement

If science is to make the progress it deserves, it must be upon the basis of a wide sympathy and understanding amongst the plain men of the earth At the lowest terms of this compact, research can obtain the adequate funds which the Smithsonian and every other scientific institution longs for, only when the public has grasped the vital importance of scientific results so thoroughly that it compels the disbursement for such purposes of the State funds which it itself contributes In other words, in these democratic days, the adequate prosecution of research is inextricably bound up with the scientific education of the people

Science and Humanism

The neglect of science by historians, and the misunderstanding of its service by representatives of labour, are familiar to most readers of Nature The new review *The Realist*, to which reference was made in our issue of April 6, p 540, contains two contributions dealing respectively with these subjects—one by Dr Singer on scientific humanism and the other by Mr John Gibson on the relations of labour and science Both describe from different points of view a state of things which our readers would wish to alter both resolve themselves ultimately into a question of education

Dr Singer starts with the astounding fact, often commented on in these columns, that our accustomed books on history, even such monumental works as the "Cambridge Modern History," ignore, for the most part completely, the rôle played by science in the historic process As he says—and it is a new way of putting it—"Had it so fallen out that Galileo and Kepler, Newton and Lavoisier and Darwin had been Persians, Turks, Indians, and Russians instead of Italians, Germans, Frenchmen, and Englishmen, it is very certain that the face of the civilised world would have been quite different from what it is Yet such names are wellnigh ignored in ordinary works of history" The 'ordinary' historian, when charged with this, says either that history is past politics, or how men have come to live together more or less peacefully in States, or, if he does not subscribe to this narrow and exploded heresy, that he does not know about science and thinks it better to leave it to those who do The latter argument, however, is not applicable to such a work as the "Cambridge Modern History," which is a composite production and might just as well contain chapters on science as it does certain chapters on literature

The right solution is one which will take years of philosophic thinking to achieve, namely, what is the place which science has taken in building up the social structure which is, as most of the historians now perceive, the proper subject of history Dr Singer therefore seems to us perfectly right in laying more stress on the introduction of science in its proper place in the presentation of general history than on the elaboration of the historic side in the teaching of science, though that also is a good thing

The article by Mr Gibson, on science and labour, is more depressing and raises another educational question of a wider kind Mr Gibson notes the almost complete absence of any knowledge or interest in science among the workmen whom he has met, and also finds dread and opposition to the spread of machinery as displacing the human worker He is probably generalising from the class of workmen—those in the building trades—who suffer most immediately from the introduction of new machines and have the least turn for mechanics The picture would not be so black if it were painted of any branch of the engineers So far as the educational question is concerned, it should be easier rather than more difficult to imbue the young workman with some knowledge and interest in science than his more lettered fellow scholar who gives so much time to literature and the study of the dead languages The boy who goes to a technical or a central school with an industrial bias—and these places are growing—has a good opportunity of approaching science at least on the practical side, and Mr Gibson's account of the young man of to-day who does all

the needed repairs to his motor bicycle or his wireless set, inspires one with some hope It is, of course, precisely by that channel that the intelligent teacher of science will approach the theoretical basis

On the question of the displacement of the man by the machine, Mr Gibson is dealing with a problem of social and economic organisation which has been with us all through the Industrial Revolution It cannot be said that we have dealt with it very wisely or successfully, and yet we are all agreed that operations which can be as efficiently performed by a machine should, in the interest alike of production and the producer, be so done Every displacement however, should be accompanied by careful provision for the displaced The social *raison d'être* of the machine is that it frees the human agent for other work, either in the further conquest of Nature or the development of his own faculties

Srinivasa Ramanujan

Collected Papers of Srinivasa Ramanujan Edited by G H Hardy, P V Seshu Aiyar and B M Wilson Pp xxxvi + 355 (Cambridge At the University Press, 1927) 30*s* net

RAMANUJAN was born in India in December 1887, came to Trinity College, Cambridge, in April 1914, was ill from May 1917 onwards, returned to India in February 1919, and died in April 1920 He was a fellow of Trinity and a fellow of the Royal Society

Ramanujan had no university education, and worked unaided in India until he was twenty seven years of age When he was sixteen he came by chance upon a copy of Carr's " Synopsis of Mathematics ", and this book, now sure of an immortality its author can scarcely have dreamt of, woke him quite suddenly to full activity A study of its contents is indispensable to any considered verdict upon Ramanujan It gives a very full account of the purely formal side of the integral calculus, containing, for example, Parseval's formula, Fourier's repeated integral, and other ' inversion formulæ ' There is also a section on the transformation of power series into continued fractions Ramanujan somehow acquired also an effectively complete knowledge of the formal side of the theory of elliptic functions (not in Carr) The matter is obscure, but this, together with what is to be found in, say, Chrystal's " Algebra ", seems to have been his complete equipment in analysis and theory of numbers It is at least certain that he knew nothing of operations with divergent series or of work on the distribution of primes Above all, he was totally ignorant of Cauchy's theorem and complex function theory

The work he published during his Indian period did not represent his best ideas, which he was probably unable to expound to the satisfaction of editors In the beginning of 1914, however, a letter from Ramanujan to Mr Hardy (then at Trinity, Cambridge) gave unmistakable evidence of his powers, and he was brought to Trinity, where he had three years of health and activity

I do not propose to discuss here in detail the work for which Ramanujan is solely responsible (a very interesting estimate is given by Prof Hardy, p xxxiv) If we leave out of account for the moment a famous paper written in collaboration with Hardy, his definite contributions to mathematics, substantial and original as they are, must, I think, take second place in general interest to the romance of his life and mathematical career, his unusual psychology, and, above all to the fascinating problem of how great a mathematician he might have become in more fortunate circumstances In saying this, of course, I am adopting the highest possible standard but no other is appropriate

Ramanujan s great gift is a formal one, he dealt in ' formulæ ' As a specimen we may take the following (which no one can ever resist quoting) If $p(n)$ is the number of ways of expressing n as a sum of positive integers (partitions of n ') then

$$p(4)+p(9)x+p(14)x^2+p(19)x^3+\dots = 5\frac{\{(1-x^5)(1-x^{10})(1-x^{15})\dots\}^5}{\{(1-x)(1-x^2)(1-x^3)\dots\}^6}$$

The great day of formulæ however, is over No one, if we are again to take the highest point of view, seems able to discover a radically new type, though Ramanujan comes near it in his work on partition series A hundred years or so ago his powers would have had ample scope Discoveries alter the general mathematical atmosphere and have very remote effects, and we are not prone to attach great weight to rediscoveries, however independent they seem How much are we to allow for this , how great a mathematician might Ramanujan have been 100 or 150 years ago , what would have happened if he had come into touch with Euler at the right moment ? How much does lack of education matter ? Was it formulæ or nothing, or did he develop in the direction he did only because of Carr's book—after all, he learned later to do new things well, and at an age mature for an

Indian? Such are the problems Ramanujan raises; and everyone has now the material to judge them. The letters and the lists of results announced without proof are the most valuable evidence; indeed, they suggest that the 'note-books' would give an even more definite picture of the essential Ramanujan, and it is very much to be hoped that the editor's project of publishing them *in extenso* will eventually be carried out.

Carr's book quite plainly gave Ramanujan both a general direction and the germs of many of his most elaborate developments. But even with these partly derivative results one is impressed by his extraordinary profusion, variety, and power. There is scarcely a field of formulæ that he has not enriched, and in which he has not revealed unsuspected possibilities. The beauty and singularity of his results are entirely uncanny. Are they odder than one would expect things selected for oddity to be? The moral seems to be that we never expect enough; the reader at any rate experiences perpetual shocks of delighted surprise. Prof. Watson and Mr. Preece have begun the heroic task of working through the unproved statements; some of their solutions have appeared recently in the *Journal of the London Mathematical Society*, and these strongly encourage the opinion that a complete analysis of his note books will prove very well worth while.

There can, however, be little doubt that the results showing the most unmistakable originality and the deepest insight are those on the distribution of primes (see pp. xxii-xxv, xxvii, 351, 352). The problems here are not in origin formal at all; they concern approximative formulæ for such things as the number of primes, or of integers expressible as the sum of two squares, less than a large number x, and the determination of the order of the errors is a major part of the theory. The subject has a subtle function theory side; it was inevitable that Ramanujan should fail here, and that his methods should lead him astray; he predicts the approximative formulæ, but is quite wrong about the orders of the errors. These problems tax the last resources of analysis, took more than a hundred years to solve, and were not solved at all before 1890; Ramanujan could not possibly have achieved complete success. What he did was to perceive that an attack on the problems could at least be begun on the formal side, and to reach a point at which the main results became plausible. The formulæ do not in the least lie on the surface, and his achievement, taken as a whole, is quite extraordinary.

If Carr's book gave Ramanujan direction, it had at least nothing to do with his *methods*, the most important of which were completely original. His intuition worked in analogies, sometimes very remote, and to an astonishing extent by empirical induction from particular numerical cases. Lacking Cauchy's theorem, he naturally dealt much in transformations and inversions of order of double integrals. But his most important weapon seems to have been a highly elaborate technique of transformation by means of divergent series and integrals. He had no strict logical justification for his operations. He was not interested in rigour, which for that matter is of secondary importance in analysis, and can be supplied, given the real idea, by any competent professional. The clear cut idea of what is *meant* by a proof, nowadays so familiar as to be taken for granted, he perhaps did not possess at all. If a significant piece of reasoning occurred somewhere, and the total mixture of evidence and intuition gave him certainty, he looked no further. It is a minor indication of his quality that he can never have *missed* Cauchy's theorem. With it he would have arrived more rapidly and conveniently at some of his results, but his own methods enabled him to survey the field with an equal comprehensiveness and as sure a grasp.

I must say something finally of the paper on partitions (pp. 276-309), written jointly with Hardy. The number $p(n)$ of partitions of n increases rapidly with n; thus

$$p(200) = 3972999029388.$$

The authors show that $p(n)$ is the integer nearest to

$$\text{(1)} \qquad \frac{1}{2\sqrt{2}} \sum_{q=1}^{\nu} \sqrt{q}\, A_q(n) \psi_q(n),$$

where $A_q(n) = \sum \omega_{p,q} e^{-2np\pi i/q}$, the sum being over p's prime to q and less than it, $\omega_{p,q}$ is a certain $24q^{\text{th}}$ root of unity, ν is of the order of $\sqrt{n}$, and

$$\psi_q(n) = \frac{d}{dn}\left(\exp\{C\sqrt{(n - \tfrac{1}{24})}/q\}\right), \quad C = \pi\sqrt{(\tfrac{2}{3})}.$$

We may take $\nu = 4$ when $n = 100$. For $n = 200$ we may take $\nu = 5$; five terms of the series (1) predict the correct value of $p(200)$. We may always take $\nu = \alpha\sqrt{n}$ (or rather the nearest integer), where α is any positive constant, provided n exceeds a value $n_0(\alpha)$ depending only on α.

The reader does not need to be told that this is a very astonishing theorem, and he will readily believe that the methods by which it was established involve a new and important principle, which has been found very powerful and fruitful in other fields. The story of the theorem is a romantic one. (To do justice to it I must infringe a little the rules

about collaborations I therefore add that Prof Hardy confirms and permits my statements of bare fact) One of Ramanujan's Indian con jectures was that the first term of (1) was a very good approximation to $p(n)$ this was established without great difficulty At this stage the $n-\frac{1}{24}$ was represented by a plain n—the distinction is irrelevant From this point the real attack begins The next step in development, not a very great one, was to treat (1) as an asymptotic ' series, of which a fixed number of terms (e g $\nu=4$) were to be taken, with an error of the order of the next term

From now to the very end Ramanujan always insisted that much more was true than had yet been established there must be a formula with error $O(1)$ " This was his most important con tribution , it was both absolutely essential and most extraordinary A severe numerical test was now made, which elicited the astonishing facts about $p(100)$ and $p(200)$ Then ν was made a function of n this *was* a very great step, and in volved new and deep function theory methods that Ramanujan obviously could not have discovered by himself The complete theorem thus emerged

The solution of the final difficulty was probably impossible, however, without one more contribution from Ramanujan, this time a perfectly characteristic one As if its analytical difficulties were not enough the theorem was entrenched also behind almost im pregnable defences of a purely formal kind The form of the function $\psi_q(n)$ is a kind of indivisible unit among many asymptotically equivalent forms it is essential to select exactly the right one Unless this is done at the outset, and the $-\frac{1}{24}$ (to say nothing of the d/dn) is an extraordinary stroke of formal genius, the complete result can never come into the picture at all There is indeed, more than a touch of real mystery If only we *knew* there was a formula with error $O(1)$, we might be forced to the correct form of ψ_q But why was Ramanujan so certain there was one ? *Theoretical* insight, to be the explanation, had to be of an order scarcely to be credited Yet it is hard to see what numerical instances could have been available to suggest so strong a result and unless the form of ψ_q were known already, *no* numerical evidence could suggest anything of the kind—there seems no escape, at least, from the conclusion that the discovery of the correct form was a single stroke of insight We owe the theorem to a singularly happy collaboration of two men, of quite unlike gifts, in which each contributed the best, most characteristic, and most fortunate work that was in him Ramanujan's genius did have this one opportunity worthy of it

The volume contains a biography by the second of the editors, and the obituary notice by Prof Hardy These give a vivid picture of Ramanujan's interesting and attractive personality The mathe matical editors have done their work most admirably It is very unobtrusive the reader is told what he wants to know at exactly the right moment and more thought and bibliographical research must have gone into it than he is likely to suspect J E LITTLEWOOD

Filterable Viruses

Filterable Viruses By Harold L Amoss, Jacques J Bronfenbrenner, Alexis Carrel, Edmund V Cowdry, Rudolf W Glaser, Ernest W Good pasture, Louis O Kunkel, Stuart Mudd, Peter K Olitsky, Thomas M Rivers Edited by Thomas M Rivers Pp ix+428+15 plates (London Baillière, Tindall and Cox, 1928) 34s net

THE nature of virus still eludes precise de finition No one knows exactly what it is, and none of the hypotheses covers all the apparent facts without a certain amount of artificial strain ing At one extreme there is the conception that a virus is a parasite, something analogous in a general way, though not necessarily closely similar to a bacterium or a protozoon, with properties appropriate to its very small size It is odd, though, if this is so, that no saprophytic virus is known We can imagine a pathogenic bacterium arising by some process of adaptation from the many similar saprophytes existing everywhere in Nature, but the viruses are always associated with living cells and have never been certainly known to multiply in their absence At the other extreme are those who look upon them as derivatives of the cells with which they are associated, possibly par ticulate but not living individual organisms The difficulty in this view is to explain the transmissi bility, the remarkable power of multiplication or increase, and the specificity revealed by serological reactions

Midway between these extremes come those who, like Boycott, regard viruses as an order of being neither wholly alive nor wholly dead, but with some of the properties of both states or, like Wollman, look upon them as altered detachable genes, capable of leaving their cells of origin and entering other similar cells, an intriguing combination of infection and heredity The parasitic conception, however, is a convenient working hypothesis Nothing certainly disproves it, and it will probably

continue to hold the field until there is conclusive evidence of the origin of a virus *de novo*, as is already suggested by the work on bacteriophage and the filterable tumours

Animal pathologists lay great stress on filterability as an important character, and so no doubt it is when it occurs But its present importance is perhaps chiefly a historical residue Even in animal virus diseases it is not a constant character, and the plant pathologist attaches little importance to it, even in diagnosis, since most of the virus diseases of plants are not transmissible by extracted juice, whether filtered or not It is possible that it may come to have a real importance as a means of distinguishing viruses which can be detached from their cells without loss of character from those which cannot, but this is still in the future One is glad to see that in the book under review the term 'filterable viruses' is used in a general non committal way to cover all the active transmissible agents which produce virus disease

The present volume is sure of a welcome, and deserves it The amount of information that has accumulated on the subject of virus diseases since Iwanowski showed, thirty seven years ago, that tobacco mosaic is filterable, is so enormous that even the specialist cannot keep abreast of it all It covers so wide a field (mammals, birds, fish, plants, insects, even bacteria) and the literature is so widely scattered that it is difficult so much as to hear of all the papers that appear, and the collection of the salient facts into a single volume is a useful piece of work Even in this volume of more than 400 pages, detailed survey has proved impracticable, and the method adopted is to select certain diseases of man, animals, fowls, etc , and treat them as typical examples of the different groups, prefacing them with some chapters of a more general nature

The first chapter, on "Some General Aspects of Filterable Viruses," by the general editor, T M Rivers, has already appeared in the *Journal of Bacteriology* It discusses in a series of short sections such questions as epidemiology, immunity, filterability, size and the like, giving briefly the ascertained facts and occasionally the theories This chapter, we think, might have been considerably expanded The book, as a whole, no doubt aims mainly, and commendably, at recapitulating established fact rather than theoretical discussion, but—to take only one example—to abandon a consideration of whether viruses are animate or inanimate, on the ground that "it leads one into the sterile discussion of what life is, a problem still in the realm of metaphysics," seems scarcely adequate

An excellent chapter follows on filters and filtration, by Stuart Mudd, practical and sane, and also salutary because many unwarranted conclusions have been drawn from experiments with filters The third chapter is by A Carrel, on tissue culture, in the study of viruses, a method likely to lead to greater results than it has produced as yet E V Cowdry contributes a cautious, well balanced, and informative discussion on intracellular pathology, with excellent illustrations, coloured and uncoloured

Then follow the special articles already referred to Poliomyelitis in man by H L Amoss, foot and mouth and vesicular stomatitis by P K Olitsky, contagious epithelioma in birds by E W Goodpasture, virus diseases of insects by R W Glaser, of plants by L O Kunkel, and of bacteria by J J Bronfenbrenner All these are authorities on the subjects of which they treat, and, although in every case a specialist will no doubt wonder at some omissions and feel disposed to quarrel with some statements made, still they do give excellent reviews of present knowledge and convenient summaries of present opinion, and that is what one hopes to find in chapters such as these They are addressed not so much to the specialist, who presumably knows the facts of his own subject, as to the semi specialist and the worker on cognate lines, who cannot easily keep in touch with current knowledge outside his own limited field This function they serve admirably The whole volume is a most useful and convenient collection of the available information on filterable viruses

J HENDERSON SMITH

Problems of Island Life

Diptera Brachycera and Athericera of the Fiji Islands based on Material in the British Museum (Natural History) By Mario Bezzi Pp viii + 220 (London British Museum (Natural History), 1928) 15s

ISLAND life presents problems of great interest to the biologist and in particular to the student of geographical distribution Among the many islands of Polynesia a great field for research awaits inquiry In so far as the insects and other invertebrates are concerned, we know as yet comparatively little respecting what peculiar forms are present, how the creatures of one group of islands differ from those of another, and from where they have been derived

The Hawaiian group is better known than any other Pacific archipelago, a fact largely due to the wisdom and foresight of those Englishmen who inaugurated the "Fauna Hawaiiensis" and saw it through to completion Its volumes form the groundwork for all subsequent progress in Hawaiian entomology, besides providing an important contribution to the problems of island life in general The work was not instituted one month too soon —in fact, species had already disappeared and become lost to science before its inception To day the spread of cultivation on the island of Oahu, for example, has practically destroyed the whole of the indigenous insect fauna over most of the terrain—what is left is mainly to be found on the forest-clad flanks of its steep mountains Without the "Fauna Hawaiiensis" we should be at a loss to day to know whether many of the insects are introduced or indigenous, and when it comes to problems of pest control this knowledge acquires added importance The work of the Percy Sladen Trust Expedition, under Prof J Stanley Gardiner, has similarly laid the foundations of our knowledge of the fauna of the Seychelles and neighbouring islands in the Indian Ocean

It is only a matter of time when Fiji Samoa, and all the larger oceanic islands will inevitably come under the influence of cultivation to the same extent as the Hawaiian group To day they are changing, and new elements are entering their fauna through the agency of increased maritime communications Sooner or later a highly composite and drastically altered fauna will result There is no doubt, therefore, if we are to have an adequate knowledge respecting the native insects and other elements of the fauna of Polynesia, every opportunity needs to be utilised, at least to collect material, before civilisation advances much further It might be feasible to circularise and impress this fact upon all resident naturalists and induce them to send specimens to our national collection It may be necessary to provide them with instructions store boxes and apparatus, but it would be worth while and the costs would be relatively trifling

The small volume by the late Prof Bezzi, now before us, consists of a series of highly technical detailed descriptions of flies from the Fiji Islands Since its author was one of the most eminent of Dipterists, it is consequently authoritative Altogether 239 species of flies are dealt with, and it is noteworthy that only 30 of them were known to exist in Fiji (including the Tonga Islands) up to the end of the year 1925 It is also interesting to note that 60 per cent of the flies enumerated are endemic to Fiji, and nearly all were previously undescribed Certain families of flies, notably the Ortalidæ, Trypetidæ, Chloropidæ, and Muscidæ, comprise, on the other hand, a good many non endemic forms, probably on account of their association with the activities of man Their distribution by commerce in fruits and other vegetable matter, or by the drifting of trees and plant debris in the sea, accounts for the presence of a considerable number Excluding the imported elements, the Fijian dipterous fauna is an endemic one of Austro Malayan origin A point of great economic importance is the fact that the Mediterranean fruit fly (*Ceratitis capitata*) is happily absent from the list, and yet it is a pest in some other Pacific islands

The Natural History Museum has done zoology a service in publishing this volume, and it is to be hoped that its appearance will stimulate the collection of further material bearing upon the unique problems of island life A D IMMS

Methods of Sea-water Biology

Handbuch der biologischen Arbeitsmethoden Herausgegeben von Prof Dr Emil Abderhalden Lieferung 256 Abt 9 *Methoden der Erforschung der Leistungen des tierischen Organismus*, Teil 5, Heft 2 *Methoden der Meerwasserbiologie* Über Kultur und Methodik beim Studium der Meerespflanzen, von Josef Schiller, Methoden der Untersuchung der Bodenfauna des Meerwassers, von Harald Blegvad Pp 181 330 +11 Tafeln (Berlin und Wien Urban und Schwarzenberg, 1928) 10 gold marks

SCHILLER'S work occupies 129 pages of this part of Abderhalden's "Handbuch," the remaining 20 with 11 tables being Blegvad's portion The former contains detailed information on the setting up of small aquaria, their aeration and temperature control Some account is given of the chemical composition of sea water and of the various salt solutions used for the culture of fresh water and marine algae, sections are devoted to the organic nutrients useful in the study of marine Chrysoand Cryptomonads and other plants, also to solid media and colloidal solutions Attention is directed to the necessity of regulating the intensity of the light, and details are given concerning the construction of various types of light filter, solid and liquid References are made in particular to Pringsheim's work on the culture of algæ, mention is made of Schott und Gen's light filters,

but the Wratten and Corning filters have been omitted

Throughout, one is struck with the fewness of the references to British and American work—but then British marine biology has been preponderatingly zoological, and Oltmanns remains the standard authority on the marine flora of a sea going nation The Americans, though active on the Pacific coast, have been late comers into this field A section is devoted to the isolation of organisms required for pure cultures and there is a figure of a pipette, with rubber teat, of quite unserviceable thinness, the centrifuge tube shown would break at the first time of using Simple forms of water sample bottles are shown, but the standard Nansen Petersen is not mentioned

The purely botanical portion is done with Teutonic thoroughness, the groups being considered one by one in great detail The reviewer confesses to a feeling of surprise at reading of the large number of algæ that have been cultivated Mention is made of Thuret's early (1854) work on the crossing of *Fucus vesiculosus* and *F serratus* also of subsequent work by Lloyd Williams and by Sauvageau Overton's (1913) work on the parthenogenesis of the ova of *Fucus*, induced artificially, has been included When it was first published, the reviewer repeated it—the experiment goes beautifully Nobody appears to have used algal material for such studies since Overton published, which is strange, since sea urchin and other animal eggs have been worked at assiduously In conclusion, the Phanerogams *Zostera* and *Posidonia* are mentioned in virtue of their marine habitat, and a long list is given of the algæ of the Adriatic, North and Baltic Seas, with their vegetation periods and ease of cultivation

The whole article constitutes a very useful compendium of the present state of knowledge on this subject

Blegvad's article deals mainly with various bottom grabs, such as that of the late Director C G Joh Petersen For quantitative work, grabs are made to cover 0 1 m^2 or, for larger animals, 1 m^2 These are described and illustrated It is hard to see the value of including pictures of a dredge swung clear for use, of a boat with square net, and of partly filled sample bottles The results obtained with the bottom grabs are of great interest A figure gives the large annual variations, from 1910 until 1922, in the population density of the sea bottom at one station in *Abra alba* and in *Solen pellucidus* The bottom fauna in Timfjord is worked out in great detail in Table 1 Other tables (plates) show pictorially the distribution of animals in the various associations (*Besiedlung*, colonisation) or communities found on different types of sea bottom These are excellent, as it is very difficult to visualise the meaning of numerical fauna lists Plate XI shows the seas surrounding Denmark stippled and marked to show the areas covered by the various communities No other seas have been worked out with such detailed accuracy This article is commendably brief, and is packed with information

Our Bookshelf

Chemical Publications their Nature and Use By Prof M G Mellon (International Chemical Series) Pp viii + 253 (New York McGraw-Hill Book Co, Inc, London McGraw-Hill Publishing Co, Ltd, 1928) 12*s* 6*d* net

To the several books and various other publications that deal specifically with the topography of the literature of chemistry is now added one which, in addition to supplying the usual kind of information and advice in the manipulation of such tools as are available—extremely valuable as both are—goes a step further, and drives its lessons home by providing material for practice in the specialised technique which is described Already, of course, chemical literature has reached such vast proportions (having grown at a rate not altogether indicative of real chemical progress) that we feel a lurking sympathy for the business man who had to give up business in order to attend to his card index Moreover, the areas of intersection of chemical and other scientific spheres have tended to enlarge and become indistinctly defined

It is not surprising, therefore, that general excursions having in view an exhaustive examination, a rapid disinterment of what in the circumstances may be buried treasure, or even a hurried survey to provide a background for some commercial decision, tend more and more to be entrusted to specialists, or at any rate practicians, in the art For exactly the same reasons it is clearly desirable that students of chemistry should find time to familiarise themselves with the records of their subject The material in this book is intended to constitute the basis of an undergraduate course

There are nine chapters, in which the development of the literature, original sources (periodicals, institutional proceedings, patents, and miscellaneous contributions), and secondary sources (periodicals and serials, bibliographies, works of reference, and text books) are discussed, and the technique of the search is described The subject is placed on a class-room basis—or rather, on a library basis—by the inclusion of fourteen groups of problems (arranged in a manner somewhat reminiscent of 'prep in the lower fourth'), in which the student is required, for example, to supply full details concerning an assigned journal, to collect, complete with 'chapter and verse,'

selected physico-chemical data, or to 'look up' an organic compound Most chemists have learned the use of the literature in the school of necessity, so that although its appearance as an exercise may seem to them somewhat strange and curious, they will all the more readily perceive the advantage of early systematic direction A A E

Radiomovies, Radiovision, Television By C Francis Jenkins Pp 143 (Washington, D C Jenkins Laboratories, 1929) 2 50 dollars

C F Jenkins, the author of this work and one of the pioneers of television, took up inventing as a profession about thirty years ago He now possesses more than four hundred patents in America and other countries, and has a private laboratory in Washington for carrying out his researches He has done an immense amount of work in developing 'radiomovies,' both by using wires (television) and by transmitting them by radio waves (radio vision)

In July last, Mr Jenkins began broadcasting radiomovies at fixed times He thus gave the amateurs something for which to 'angle' A few weeks later more than a hundred amateurs had finished their receivers and could reckon with certainty on getting their regular picture stories At first only silhouettes were broadcast, as it was essential to keep the frequency band less than ten kilocycles The Radio Commission has now assigned to his company a band 100 kilocycles wide (4900 5000 kilocycles), and at the present time thousands of amateurs receive half tone 'movies' on their receiving picture sets The pictures transmitted are mainly pantomime pictures, but Mr Jenkins expects that his new machine, which is practically finished, will revolutionise the art and make it possible to transmit pictures of theatrical performances, outdoor games, inaugural ceremonies, and even grand opera with full vocal accompaniment

This book describes how to make and work a receiving set It concludes with descriptions of other of Mr Jenkins's inventions, including a landing altimeter which enables an airman to glide his machine to a landing in a fog, a novel method of predicting hurricanes by means of the snapping noises they produce in a radio receiver, and a method of guiding an aeroplane on its course in a fog He is the inventor of the motion picture projector, the principle of which is in use all over the world The Franklin Institute awarded him a gold medal for this invention in 1895

The Journal of the Institute of Metals Vol 40 Edited by G Shaw Scott Pp xii + 877 + 37 plates (London The Institute of Metals, 1928) 31*s* 6*d* net

Reports on the corrosion of condenser tubes and on the properties of alloys for die casting occupy a prominent position in the new volume The work on corrosion has had a definite result in showing that cupro-nickel and a special aluminium brass have a high resistance to attack by streams of air bubbles carried off by the water, perhaps the most frequent cause of damage. The researches of this committee have proved particularly valuable to the tube industry

Die casting has made great progress in recent years, although even now it is far less used in Great Britain than in America, and the present papers contain valuable information as to the metals best suited to this class of work W Hume Rothery describes the methods most suitable for the preparation and study of alloys containing highly reactive metals, such as sodium and calcium, and F Hargreaves continues his investigations of alloys which are softened by cold working instead of being hardened An example of the detailed study of a complex alloy system is that of the alloys of aluminium with copper, silicon, and iron by A G C Gwyer, H W L Philips, and L Mann, illustrated by very good photomicrographs and by numerous diagrams Under ordinary conditions of cooling, these alloys depart considerably from equilibrium, so that they are used in a metastable condition An unexpected result is recorded by D R Tullis, who has freed aluminium alloys from the gases causing unsoundness by passing a stream of chlorine through the molten metal, this process, unpromising at first sight, having proved to be technically successful

The volume contains many other papers and the usual abstracts

Travels and Settlements of Early Man a Study of the Origins of Human Progress By T S Foster Pp 320 (London Ernest Benn, Ltd , 1929) 21*s* net

Mr Foster has worked over the data of palæontology and prehistoric archæology in their bearing upon the distribution of man with considerable ingenuity, and still greater enthusiasm, which have involved him in frequent departures from the orthodox view He is both stimulating and provocative He is an ardent supporter of what he calls the Anatolian strain, that is, a race originating in the Anatolian plateau of what is more usually called the Armenoid type, as a factor in the development of civilisation He has allowed full play to his theory when working out racial strains in the culture of the Pacific Although it cannot be said that this is entirely assumption, the evidence is a very slender support for so elaborate a superstructure His view of the origin and growth of American culture depends upon the acceptance of the Calaveras and New Jersey skulls—which are more than doubtful—and the Central and South American early civilisations seem to be left hanging in the air

New Worlds for Old the Realm of Modern Physics By Robert G Lunnon Pp v + 106 (London Methuen and Co , Ltd , 1928) 2*s* 6*d* net

This little book is intended for those of the general public who are not acquainted with the modern developments of physics It is a perfectly accurate, though necessarily incomplete, account of the discoveries of the last twenty five years The writing is most suitable for a book of its kind, and the average reader is not likely to arrive at false conclusions, as is so often the case, through the fact that the terminology is beyond him

Letters to the Editor

The Nature of the Penetrating Radiation

UP to the present time the view that the penetrating radiation consists of short gamma rays has been prevalent chiefly because the large penetrating power which these rays possess is associated with radiation of gamma ray type Our recent experiments however indicate that this radiation is of corpuscular nature

The experimental arrangement consisted simply of two tube counters of the type recently developed by Geiger and Muller (*Die Naturwiss* **16**, 617 1928) which were placed above one another at some distance apart in a space screened by 6 cm of lead and 5 cm of iron Each of the counters was connected to an electrometer and the deflections of the two electrometers which were due chiefly to the penetrating radiation (Geiger *Phys Zeitschr* **29** 839 1928) were registered side by side on a moving film With this arrangement a considerable number of simultaneous deflections of both instruments was recorded For small distances between the counters up to about 20 per cent of the total number of deflections of one counter were coincident pairs This percentage is so great that it must be explained on the basis that coincidences occur if the same corpuscular ray enters both counters

Two hypotheses may be made concerning the origin of this corpuscular radiation One is that the primary radiation may be of the gamma type and the coincidences the result of secondary electrons In this case one would expect the corpuscular rays to be more easily absorbed than the penetrating radiation that caused them The alternative is that the penetrating radiation is really of corpuscular nature in which case agreement should exist between the absorption coefficient of the rays causing the coincident deflections and that directly measured for the penetrating radiation itself

In order to distinguish between these alternatives a block of gold 4 1 cm thick was placed between the counters the diminution in the number of coincidences thereby giving a measure of the absorption of the corpuscular rays The first attempts were made in a laboratory of the Reichsanstalt where the thick floors and ceilings of the rooms above us greatly hardened the radiation There was no definite diminution in the number of coincident pairs under these conditions We then repeated the experiment on the roof of the building with the lid of the screen removed Under these conditions the unfiltered radiation from above acted directly on the counters and a definite diminution in the number of coincidences was observed on introducing the gold block The observed difference gives (μ/ρ) Au $= (3\ 6 \pm 0\ 5) \times 10^{-3}$ for the mass absorption coefficient This value agrees well with that measured directly for the unfiltered cosmic rays We conclude from these data that the penetrating radiation is not of gamma but of corpuscular type

The complete description and discussion of these experiments will appear in the *Zeitschrift fur Physik*

Temperature Conditions in the Suez Canal, July December 1928

THE study of the temperatures met with in the Suez Canal is invested with more than ordinary interest in view of the linkage affected between two different sea areas and the possibilities of an exchange of faunas

The Cambridge expedition to the Suez Canal (*Transactions of the Zoological Society* 1927) has shown that more marine animals have moved from the Red Sea to the Mediterranean than from the Mediterranean to the Red Sea The expedition also published valuable evidence to show that for most of the year the canal water was under the influence of a slow residual drift from the Red Sea This however was reversed during the months of the Nile flood

In studying the question of the migration of young or drifting organisms through the canal temperature has very rightly been considered as of first importance as a possible limiting factor

The only series of data concerning the temperatures of the canal that offer anything like a contemporaneous series are those taken by the *Pola* expedition in October 1895 and May 1896

The present observations were all made within two days on each occasion and so were very nearly simultaneous

The following list shows the positions at which they were made

Suez Canal Station 1 Opposite entrance buoy to Suez Canal Port Said
2 Opposite Canal Company s signal station at Ballah
3 1 kilometre S E of the Canal Company s landing stage at Ismailia
4 Opposite the Northern Light Buoy of the Great Bitter Lakes
5 Kilometre 130 of the Canal
6 Opposite the last buoy but one of the Suez Canal at Suez

It is the intention of the directorate of Fisheries Research Coastguards and Fisheries Service to take routine temperature and salinity observations from these positions over a run of years

The surface observations for July 1928 and February March 1929 are shown here

Station		S C 1	2	3	4	5	6
Date		19 7 28	19 7 28	19 7 28	20 7 28	20 7 28	20 7 28
Time		1043	1450	1637	1228	1628	1855
Temperature	C	28 92	29 28	29 60	29 18	28 85	26 55
Date		28 2 29	28 2 29	28 2 29	1 3 29	1 3 29	1 3 29
Time		1034	1505	1705	1139	1843	1753
Temperature	C	14 32	14 70	14 96	15 25	17 85	17 53

A Nansen Petersen insulated closing bottle was used with a Schmidt thermometer

Examining the Cambridge and *Pola* expedition temperatures one is struck by the anomaly of higher figures for Port Said than for Suez This same condition is shown in my figures for July In February–March however, there is a higher temperature at Suez than at Port Said and from Station S C 2 to Suez there is a steady rise along the whole length of the canal

There seems to be then a higher temperature at the northern end of the canal than the southern in summer, and a higher temperature at the southern than the northern end in winter This relatively higher summer temperature of the water at Port Said is quite inexplicable on ordinary considerations of position and I am led to suggest the following explanation

The sea in the neighbourhood of Port Said is constantly receiving Nile water This comes out through a large shallow lake—Lake Menzaleh—and in the summer and autumn through the Damietta mouth of the Nile Travelling through a thousand miles of heated desert—partly discharging through a shallow lake which is rapidly heated by the sun—the effluent water of the Egyptian Nile is much hotter than that of the Mediterranean Sea in the summer

The order of the temperatures in these delta lakes is well shown by Paget (Fisheries Report of Egypt, 1921) It will be seen that the average monthly temperature in August and July is 30° C

Anti-Knock Ratings of Pure Hydrocarbons

PROF NASH and Mr Howes emphasise the fact that whereas their figures for trimethylethylene and diamylene were quoted for twenty per cent volume concentration, our own were for twenty per cent weight concentration From curves obtained for these hydrocarbons reproduced in Fig 1, it is clear

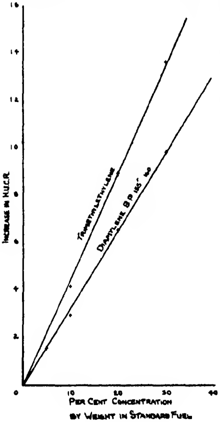

FIG 1

that over the range examined the relationship between weight-concentration and increase in H U C R is linear Knowing the specific gravities, it is a matter of simple calculation to show that the discrepancy cannot be due to our use of what we regard as the only rational procedure The specific gravity of the standard fuel was 0·725 at 60° F

So far as the possible effects of volatility are concerned, all tests at these laboratories are carried out with sufficient intake air, heating, and jacket and head temperature to ensure that no appreciable difference in anti knock rating is found with any further heating whether low boiling gasolines or heavy kerosines are being tested

The recent recommendations made by Campbell Lovell, and Boyd regarding the importance of making all comparisons at the mixture strength which gives maximum pinking have been in use here for upwards of two years The Armstrong engine developed independently in these laboratories while their work was in progress includes both variable compression head and bouncing pin

In order to find definitely whether differences in volatility are the cause of discrepancies between one fuel and another, experiments have been carried out with

1 Standard heating conditions and compression adjusted to suit the sample

2 Evaporative cooling, high compression and throttling to control the pinking as is the practice when using the Delco engine

The mean results were identical, although the values of single readings using the second set of conditions were more erratic owing probably to the method of cooling which tends to induce stray hot spots

We feel that possibly complete agreement might be reached on those points still in doubt if tests were carried out using a common supply of trimethylethylene and diamylene in both engines, employing a range of air fuel ratios

In the case of the Ricardo E 5 engine and the Armstrong engine used in this laboratory, the effect of air fuel ratio has already been thoroughly studied Similar experiments could be made without alteration to apparatus on the Delco plant, and we have no doubt concerning the ultimate results

Confirmation of the accuracy of our figures is afforded by the fact that substantially identical values are obtained using such a wide range of research engines as

(a) The Thornycroft overhead valve engine of 1025 c c capacity (b) The Ricardo sleeve valve engine of 350 c c capacity (c) The Armstrong engine with a fixed ratio head (d) The Armstrong engine with a variable compression head

S F BIRCH
R STANSFIELD

Anglo Persian Oil Co , Ltd ,
Meadhurst Laboratories,
Sunbury on Thames

WE would thank the Editor of NATURE for kindly allowing us to reply to the above letter of Messrs Birch and Stansfield, but feel that we must not trespass on the space of this journal any further in that all contribution to our knowledge of the subject under discussion ceased with our letter which appeared in the issue of April 6

In our previous communication no suggestion was made that the difference in the results obtained for diamylene and trimethylethylene was due entirely to the fact that Messrs Birch and Stansfield employed concentrations by weight, whereas we used concentrations by volume Nevertheless, the fact must necessarily contribute to the discrepancy

It is also not impossible that the samples of diamylene as used by Messrs Birch and Stansfield and ourselves were not chemically identical The boiling ranges were not the same, and seeing that the diamylene as made from trimethylethylene is

probably not a single chemical entity but a mixture of isomers, the composition of the diamylene produced may vary with the method and condition of the particular polymerising reaction used Diamylene, prepared in this way, cannot be chemically described with the same certainty that would be associated with trimethylethylene

With regard to the other point raised, it is well known that differences in results obtained by different workers with different engines may be due to technique and design, and it is well realised that concordant results will never be obtained until a standard method of test is employed by all laboratories

We welcome Messrs Birch and Stansfield's suggestion of carrying out tests using a common supply of trimethylethylene and diamylene in both types of engine, as we feel that such collaboration would result in a much greater advance than further correspondence at this stage of our knowledge

In the meantime, it is known to us that research workers in the United States have been carrying out similar investigations for some years, and now that the results of our work have been disclosed, it would add materially to our knowledge of the subject if they would publish their conclusions

Rise and Fall of the Tides

From information published by the Hydrographic Department of the Admiralty it is possible to find the rise and fall of the tides and the times of high and low water on almost all the coasts of the world except in the extreme north and south latitudes

The periods of the tides depend on astronomical conditions, and the many terms which are involved have been investigated The periods, however, furnish no information as to the tidal range, that is, the difference in elevation between high and low water

A very simple calculation, however, depending merely on the masses and distances of the tide producing bodies, suffices to show that were the earth fluid and devoid of rigidity, then the difference between the semi axes of the tidal spheroid would be of the order of one in twenty million, or about a foot at the earth's surface

From the Admiralty Tables it will be seen that on coasts facing the open ocean the observed rise and fall in relation to the land lies somewhere between 5 and 10 feet on the average, but that where the coast line is complicated and the water shoals gradually, far greater variations appear, which may range from 0 to 50 feet

It is not necessary to go outside the English and neighbouring coasts to find examples of such differences For example, near the mouth of the English Channel the rise and fall is about 20 ft , in the Bristol Channel, nearly 50 ft , at Portland, about 5 ft , and in the neighbourhood of Mt St Michel, 50 ft These large differences may be accounted for in part by interference, that is, by the tide reaching the position of observation by different routes of unequal effective lengths, or again, resonance may be involved, as is apparently the case in the English Channel, where high and low water at the opposite ends occur at the same time

The most general cause, however, which operates to make the coastal rise and fall so much larger than the equilibrium tide in the open ocean, is the gradual concentration of energy which occurs when a wave of small amplitude but large mass travels from deep to shallow water

Among many familiar examples which depend on the same sort of concentration of a constant amount of energy in a gradually diminishing mass, may be mentioned the cracking of whips, flapping of flags and sails, throwing a rope, and throwing a fly, and I will add three more where the results can be readily calculated

(1) A heavy flexible cord passes through a hole in a fixed horizontal plate That part of the cord which hangs free below the plate is given a small horizontal velocity and swings as a pendulum The cord is then drawn upwards through the plate Above the plate the cord is stationary, and the energy it contained is transferred to the part still hanging free, the mass of which continually decreases with the length of the free part Hence the horizontal velocity of that part tends to become infinite when the length vanishes

(2) A light reel is wound with a few turns of massive but flexible cord and placed on a horizontal table to which one end of the cord is attached Two forces act on the reel, both tending to make it roll away from the point of attachment of the cord to the table, namely (*a*) the weight of one half turn of the cord acting at half the radius of the reel, and (*b*) the horizontal component due to the centrifugal force of the mass of half a turn of the cord at the velocity of the rotation of the reel As the rolling proceeds the cord is left at rest on the table, and the energy is gradually concentrated in the remaining turns Hence the angular velocity tends to become infinite as the last part of the cord leaves the reel

(3) An endless massive but flexible belt connects two wheels lying in the same plane The wheels are given a certain spin, and both parts of the belt are then cut at the same instant half way between the wheels What is the subsequent motion of the two parts of the belt ? Before cutting, the total momentum is zero If the line joining the centres of the wheels is taken as the axis of X, the momentum parallel to X remains zero for both parts, but after the cut is made is equal and opposite in direction for the two parts its amount being the component parallel to Y of those parts of the belt which are in contact with the circumference of the wheels The centres of inertia of each part remain at a constant distance from Y, but move at a constant speed parallel to Y, one to the right and the other to the left of X according to the direction of the spin It will be found that the cut parts of the belt assume in succession the shape of alternate right handed and left handed pot hooks, becoming straight lines for a single instant with an infinite terminal velocity parallel to Y

How very large the velocities attained by the concentration of energy may become in real cases is shown by the crack of a whip, where the few feet per second originally given to the lash rises to explosive velocity at the last instant

The gradual increase in the height of gentle waves as they approach a shelving beach is familiar to most people, and the same sort of action must accompany the small disturbance which constitutes the tidal wave in deep water as the latter shoals

What the equilibrium rise and fall relative to the floor of the deep sea really is, is quite unknown either by observation or by theory

In the *Phil Mag* (vol 50, pp 228, 278) there are papers by Sir G B Airy and Sir William Thomson which touch on this subject and on Laplace's theory of the tides Airy objects to some of Laplace's work which is upheld by Sir William Thomson

Laplace's spherical harmonics are so general as (if the restriction is not specially introduced) to cover the introduction or withdrawal of fluid at the poles —the condition of constancy of fluid volume was in

effect introduced by Laplace, and this Airy calls a "singular and unwarranted principle" Sir William Thomson says this unwarranted principle is in fact an "exquisitely subtle" method by which Laplace determined a certain constant, and Airy rejoins, "I look on Laplace's process as a mere sport with symbols and on Laplace's conclusion as a grievous error" Whether, however, Laplace is right or wrong, his conclusion applies to an ocean covering the whole surface of the earth, and would not help to determine the motion of the fluid as actually distributed in the existing seas

The question of the earth's rigidity also would have to be settled before any theory could give a quantitative estimate of the true amplitude of the equilibrium tide

Sir William Thomson (Thomson and Tait's "Natural Philosophy") states that unless the rigidity of the earth was at least as great as that of iron or glass, the tidal rise and fall would not be so great as it actually is In view, however, of the want of deep sea observations and of the amplification which occurs near a coast line, the necessity for such rigidity does not seem to be proved

I think the only satisfactory way to ascertain the amplitude of the tides in the deep ocean is by direct measurement, and though this presents some practical difficulties, it ought not to be impossible

Evolution through Adaptation

DR BATHER'S lecture on "Evolution through Adaptation," printed in NATURE of Mar 30, bristles with debateable points, but I will select a cardinal one which appears to present a fundamental difficulty in his theory He speaks of the changes of depth and salinity in the waters which have taken place in geological time and draws the conclusion "that the surroundings of a race are continuously altering, the race has perpetually to catch up with the change" But even if the small changes that have taken place in the oceanic environment could account for the trend of evolution, for example, from an Asteroid to an Echinoid form in the Echinodermata, how could be explained the persistence of the original Asteroid type practically unchanged? The race has not changed, if certain members or groups of it have

Dr Bather points out that "there is some tendency for change of form and structure to proceed in a definite direction," but he goes much further in stating that "the direction will accord with the environment" Apart from lethal factors in inheritance and non viable monsters, what evidence is there that new forms in animal evolution are necessarily more in harmony with their environment than were and are the forms from which they arose? For example, many Echinoid and Asteroid forms share the same environment in the sea, but the Echinoid type is believed to have evolved from primitive Asteroidea How does the Echinoid trend of evolution accord better than does the Asteroid with the environment which they both share? Migration as a factor in isolation of species can be ruled out, of course, if the original and the 'evolving' line have always shared the same environment

The mutations required by Dr Bather's theories can of course be admitted, as they can be seen and investigated, but they only "provide that fundamental premise from which, *in combination with a varying environment* [italics mine], one can deduce irreversibility of evolution and orthogenetic trends" This would be true only if it could be shown that the varying environment favoured the new forms at the expense of the old, but actually the older forms are often as well adapted to the varying environment as are the new ones Another objection is that, while the slight changes that have taken place in the physical and chemical constitution of the ocean would affect such processes as fertilisation and early development in various ways, it is difficult to imagine how such changes can have directed the general "orthogenetic trends" in adult oceanic forms Furthermore, the persistence of primitive or early forms in the same environment is evidence against such a view

J S DUNKERLY

IN speaking of "Dr Bather's" theory and theories, Prof Dunkerly pays me too much honour That portion of my discourse which appeared in NATURE attempted a critical inquiry into other people's theories and a possible explanation of certain difficulties that they presented to my mind To Prof Dunkerly's mind the main theory presents yet another difficulty He admits, apparently, the fact of evolution, and he admits some change of environment, but he urges (I understand), first, that the changes of environment are too slight to produce the great evolutionary changes seen along certain lines, secondly, that if they were a *vera causa* they would have affected all lines of descent in a more equal degree

It is rather late in the day to be answering arguments of this kind, and space could not be afforded in NATURE for their adequate discussion May I suggest, first, that Prof Dunkerly underestimates the differences and the changes in the environment of sea animals? If he derives his conception from a single summarising sentence in my discourse, I would remind him that two thirds of that discourse (not reported in NATURE) was devoted to an illustrated account of some among the numerous and varied habitats, conditions, and modes of life that a single class of marine invertebrates (and a statozoic class at that) has come to fill during its long history It was emphasised that a single small patch of sea floor, which we speak of roughly as sand or sea weed or reef and so forth, really comprises many habitats On the other hand, it was urged that, just as one cannot envisage a living creature apart from its environment, so one should not conceive of the environment without the reaction of the creature, further, that the whole creature constitutes the environment of any one of its parts

Consider 'migrations,' on which Prof Dunkerly seems to misapprehend me Surveys of the sea floor, notably by the Danes, have shown that the immigration or emigration of a single species from or to a faunal assemblage on a small patch must, and does, affect the life of all the other species, although purely physical conditions are unaltered Or take mutation (which Prof Dunkerly admits) and consider the Cladocera mutant found by Banta and Wood (see NATURE, Oct 29, 1927, p 632), here is a form that can live only at a temperature higher than the normal, and if it does find a warmer pool it will be preserved as a race adapted to a new environment This does not mean that the original race will perish Why starfishes should disappear because sea urchins have (according to Prof Dunkerly) been evolved from them, I quite fail to understand They fill different places in the economy of Nature, and to say that any of them "share the same environment" is scarcely so true as would be a like statement about a groom and his horse I wonder what my friend Dr W K,

Spencer will say to the assertion that the original Asteroid type has persisted unchanged

Prof Dunkerly tells us that changes in the ocean water would affect fertilisation and early development I said nothing about this, but what difficulty is there in supposing that embryonic change affects the adult history? We all know that it does, and the results might manifest just as much regular seriation as appears in any alleged orthogenetic trend However, I do not remember touching on this in that part of the discourse which Prof Dunkerly has been so good as to discuss

F A BATHER

The Fine Structure of the Normal Scattered Molybdenum $K\alpha$-Radiation from Graphite

IN the September issue, 1928, of the *Physical Review*, B Davis and D P Mitchell reported an experimental investigation of the molybdenum $K\alpha$ radiation scattered by graphite with the aid of an ionisation spectrometer In their work it is stated that the normal scattered radiation should have a much more

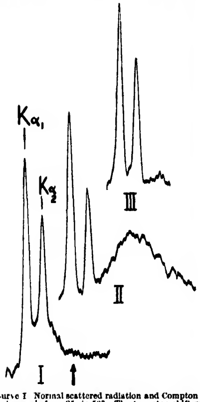

FIG 1—Curve I Normal scattered radiation and Compton scattering Scattering angle from 25 to 50° The Compton shift ranges from about 2 to 9 X units
Curve II Normal scattered radiation and Compton scattering Scattering angle from 45 to 130 The Compton shift ranges from about 7 to 40 X units
Curve III Direct radiation from molybdenum anticathode

complicated structure than the primary radiation Instead of the one $K\alpha_1$ line they find four lines one in the same position as the $K\alpha_1$ line and three lines shifted to the long wave length side by 1 2, 2, 11 3 X units respectively, the distance between the $K\alpha_1$ and $K\alpha_2$ being 4 28 X units As these shifts correspond more or less accurately to the L_{III}, L_I, and K level of the carbon atom, the effect reminds one of the well known Raman effect in the optical region

Because of the high theoretical importance of these experiments, we have tried to repeat them, using the photographic method, but we failed to detect any difference at all between the structure of the primary radiation and that of the 'undisplaced' scattered line In the meantime, Ehrenberg (*Zs f Phys*, **53**, 234, 1929) published an analogous negative result Still, we think it worth while to give a short discussion of our work in view of the importance of the problem in question

The spectrograph used was of the Siegbahn type, calcite was used as analysing crystal, the dispersion was such that the distance between the $K\alpha$ lines was 0 19 mm on the photographic plate The scattering graphite was put on the cathode inside the X ray tube, the alternating tension was 35 kv eff, the current 25 ma By taking control photographs it was ascertained that only the radiation scattered by the graphite could reach the photographic plate All the photographs taken were registered with a photometer of the Moll type (see Fig 1) Plate I was taken with the graphite at a distance from 5 to 15 mm from the anticathode focus The time of exposure was 35 hours At the small scattering angles from 25° to 50°, the Compton scattering is confused with the normal scattered lines At a distance, however, of 11 3 X units from the normal $K\alpha_1$ line where Davis and Mitchell found their weakest component of the scattered complex line (see arrow to curve I), we see that there cannot be any line with an intensity of more than 2 per cent of that of the scattered $K\alpha_1$ line Plate II was taken with the graphite at a distance from 15 to 20 mm from the focus The time of exposure was 75 hours On this plate the region between the $K\alpha_1$ and $K\alpha_2$ is wholly free from Compton radiation In this region Davis and Mitchell found two other components of the complex line From a comparison, however, of curve II with curve III, which relates to the spectrum of the direct radiation, we conclude that there seems to be no essential difference at all between the normal scattered $K\alpha$ doublet and the direct radiation

It might be remembered that if there should exist in the X ray spectrum something analogous to the Raman effect in the optical region, we should expect this to give rise not to lines but to a *continuous* spectrum, which we should not be able to detect with the means used in our experiments

Variation of Conductivity of the Upper Atmosphere

MEASUREMENTS of the height of the base of the aurora in northern Norway by C Störmer (*Geofys Publ*, I, No 5) and by L Vegard and O Krogness (*Geofys Publ*, I, No 1) show that a considerable number of the bases are situated at heights of about 100 km and about 106 km (compare the frequency curve, Fig 18, *Geofys Publ*, I, No 1, p 101) In treating 1737 base heights between 90 and 120 km it was found from the frequency curve that during ebb tide in the atmosphere the maximum at 100 km was predominant, while during flood tide the maximum at 106 km was predominant Further investigations have shown that the maxima of the frequency curve are to be considered as displacements of one and the same maximum. From this we conclude that, as regards the locality considered, the mass of air situated above 100 km at ebb tide is the same

as the mass of air situated above 106 km at flood tide

When adopting all the assumptions and results given in "The Propagation of Radio Waves" by P O Pedersen (Copenhagen, 1927), it is possible to show how the conductivity of the upper atmosphere (130 160 km) is influenced by the different states during ebb tide and flood tide Let us assume that the mass of air above a certain height varies with height in accordance with an exponential function, and let us consider, within the conducting layer, a thin layer under normal conditions and with a certain conductivity Then the problem consists in finding the variation of the conductivity caused by the atmospheric tide On account of the slower decrease in the vertical direction of the mass of air above a certain height, a thin layer with the same electric properties as the above mentioned thin layer will grow thicker at flood tide, while at ebb tide a corresponding thin layer will grow thinner The total conductivity will therefore vary according to the atmospheric tide For the place of observation (70° northern latitude), the total conductivity is found to be 4 3 per cent greater at flood tide than at ebb tide

Considering the lunar diurnal magnetic variation as a variation caused in the solar diurnal variation by tidal forces, and supposing proportionality between the conductivity in the upper atmosphere and the magnitude of magnetic variations (S Chapman), it is found from the variations of the magnetic declination that near the equator (Batavia) the conductivity at flood tide is 21 per cent higher than at ebb tide For latitude 70° an increase of 2 5 per cent in the conductivity from ebb tide to flood tide is to be expected The discrepancy with the above result is removed when, instead of a supposed temperature of the stratosphere of −54° C, a temperature of −78° C is used, after Dobson (*Proc Roy Soc*, A, vol 103, pp 339 342) such a temperature of the stratosphere may be possible during the nights in which the measurements of the base heights of the aurora have taken place A consequence of the above is that the height of the conducting layer will vary during the lunar day In latitude 45° a variation of 25 per cent from the mean height may be expected, a point on which the investigation by radio waves may be able to throw some light

Summarising, it may be said that the heights of the base of the aurora are able to give information on the tide of the upper atmosphere and thereby on the variation of the electric conductivity in the regions considered, further, that certain observed magnetic variations seem to confirm the result found The existence of a resulting enormous variation of the height of the conducting layer may be tested by means of radio waves

A Violation of the Selection Principle for the Principal Quantum Number

ONE of the selection principles, for the case of X ray spectra, states that the principal quantum number must change in any electron transition A thorough investigation was carried out by Coster (*Phil Mag*, **43**, p 1070, 1922) to determine if lines could be found corresponding to electron transitions between L levels, but no such lines were observed No violations of the principal quantum number selection rule have yet been found By using the grating method, Thibaud and Soltan (*Journal de Physique*, **8**, p 485, 1927 *Phys Zeit*, **29**, p 241, 1928) found two new lines for the elements tantalum (73), tungsten (74), platinum (78), and gold (79), and they also found that the values of ν/R for these lines corresponded approximately to those given by Bohr

and Coster for $N_{IV}\ N_{VI,\ VII}$ and $N_{V}\ N_{VI\ VII}$ respectively, but, due to the inaccuracy of the values for the energy levels, especially for the O_{I} and $O_{II\ III}$ levels, they were not able to reach any definite conclusions In a later paper, however, Thibaud (*J O S A and R S I*, **17**, p 145, 1928) ascribes the origin of the two new lines to transitions between the O (probably $O_{II,\ III}$) level and the N_{IV} and N_{V} levels

I have recently made some careful measurements in the L series, the results of which make possible a more accurate determination of the values of ν/R for the levels in question These values, as well as those of Bohr and Coster, are given in the table above with the values of ν/R for the two newly discovered lines Judged from these new values, it would seem just as likely that the doublets found by Thibaud and Soltan are due to the transitions $N_{IV}\ N_{VI}$ and $N_{V}\ N_{VI\ VII}$ This would then be the first experimental evidence of X ray transitions within levels of the same principal quantum number

Combustion of Rigidly Dried Carbonic Oxide-Oxygen Mixtures

THE paragraph in NATURE of April 13, p 584, referring to my paper on 'The Combustion of Well dried Carbon Monoxide and Oxygen Mixtures" in last month's *Proceedings of the Royal Society*, contains a statement which, if allowed to pass uncorrected, might convey a wrong impression

It is scarcely true to say that our previous experiments on the combustion of six months phosphoric anhydride dried mixtures of carbonic oxide and oxygen had been criticised ' on the grounds that inadequate precautions had been taken to remove occluded hydrogen from the platinum electrodes between which the igniting spark was passed,' although it may be that in NATURE of Sept 24, 1927, Prof H E Armstrong had queried whether possibly "hydrogen, imprisoned in the platinum electrodes" had been "extruded into the gas '

In describing, in my recent paper, our further experiments—the object of which was to test whether a prolongation of the phosphoric anhydride drying up to 550, 750, or even 1000 days (instead of the former 170 220 days) would make any difference to the results—I was careful to explain (1) that, in all the previous experiments, the electrodes had been 'glowed out' repeatedly in a high vacuum for many hours (at least 20 in all), so as to remove occluded hydrogen from them, and (2) that, in the further ones, the additional precaution had been taken of electrically 'glowing out' the electrodes in oxygen at low pressure, as well as in a high vacuum, both of which operations were continued many hours

I do not think there can be any reasonable doubt of the adequacy of the measures taken in the previous experiments to remove occluded hydrogen from the platinum electrodes, in the later ones, the further precaution referred to was taken merely to make assurance doubly sure', and, seeing that the results of the two series did not differ in any material respect, the adequacy of all precautions in both is assured Indeed, the fact that in both series condenser discharge sparks of anything up to 0 5 micro farad at 1000 volts were repeatedly passed (between platinum balled electrodes) through the phosphoric anhydride dried medium, without even the faintest sign of ignition being discernible photographically, may be regarded as a conclusive test, not only of its extreme dryness, but also of the total exclusion of hydrogen from it

The experimental results now enable us to say quite definitely (1) that a highly purified $2CO + O_2$ mixture which, under all necessary precautions, has been rigidly dried to the utmost limit possible with re distilled and highly purified phosphoric anhydride, will still explode and propagate flame provided that a sufficiently powerful igniting spark is used, and (2) that with platinum balled electrodes the minimum condenser discharge spark required is about 0 75 microfarad at 1000 volts (energy = about 0 75 Joule)

Titanium Oxide Bands in the Orange, Red, and Infra-Red Region

BANDS in the region of λ5600 to λ8000 have been analysed into at least two systems, distinct from that of the blue green region, previously analysed by Birge and Christy (*Phys Rev*, vol 29, p 212, 1927 Abstract NATURE, vol 122, p 205, 1928) One of these in the orange is a singlet system due to the electronic transition ${}^1P - {}^1S$, the other a triplet system in the red and infra red due to the transition ${}^3S - {}^3P$ Of the former only one sequence has yet been found, of the latter, four have been determined, namely, the (0, 1), (0, 0), (1, 0) and (2, 0), the $\Delta\nu$ separations of the triplet heads of the (0, 0) sequence being 66 7 and 74 6 cm $^{-1}$ respectively

The molecular constants, determined from the vibrational analysis of the triplet system, show that in the final state the vibrational frequency of the rotationless molecule with infinitesimal amplitude of vibration is the same as in the blue green system, and that thus their final energy level, ${}^3P$, is the same Further, since the separation of the triplets of red infra red system pertains to this final level, it pertains also to the final level of the blue green system

Analysis of the other bands found in the red is in progress

Ozone Absorption during Long Arctic Night

I HAVE been trying for the past ten years to interest the astronomers in having photographs of stellar spectra made during the long arctic or antarctic night, on the chance that the ultra violet cut off due to ozone may be less powerful, and I mentioned it to Prof Russell last spring I have always emphasised the importance of choosing a station so situated that there will be a minimum chance that ozone formed in the illuminated regions will be carried over into the dark region by atmospheric circulation Information regarding the direction and velocity of the upper atmospheric current will be necessary in choosing the site It should certainly be nearer the pole than the station occupied by Prof Rosseland (NATURE, Feb 9, p 207), for the sun at noon was only three or four degrees below the horizon, and the air five miles above the surface was in full sunlight, as Prof Russell pointed out to me His negative result I do not regard as decisive, though I am not very hopeful that much or any extension of the spectrum will be found, as ozone is fairly stable An objective prism pointed at the pole star seems the simplest device

Lengthened Chain Compounds of Sulphur with Platinum

IN NATURE (Jan 22, 1927, p 124) a lengthened chain compound of sulphur of the formula $BrC_2H_4(SC_2H_4)_{48}Br$, as also another of sulphonium sulphur having so high a molecular weight as 3472, have been described

Recently, in collaboration with K C Bose Rây, I have prepared another series of complex sulphur platinum chain compounds (*Zeit anorg Chem*, Bd 178, p 329, 1929) the first member of which has the formula Pt_2Cl, $2(C_2H_5)_2S_2$, $2NH_3$, $6H_2O$, and the last $Pt_{13}Cl$, $10(C_2H_5)_2S_2$, $2C_2H_5NH_2$, $8H_2O$, with a molecular weight as high as 4050 5 This is perhaps the only example as yet known of a metallic compound synthesised in the laboratory and possessing such a high molecular weight

Science and Hypothesis

By Sir OLIVER LODGE, F R S

RECENT speculations in mathematical physics, and acquiescence in treatment in terms of unimaginable abstractions, have raised a general question about the use of hypothesis as a means of co-ordinating observations, stimulating experiment, and paving the way for a theory It is possible to experiment not only in the laboratory with matter, but in the study also, with symbols and a great deal of modern mathematics is of an experimental character A hypothesis is boldly made, some indication of its plausibility having been detected by a flash of genius, it is then developed and its consequences worked out If the consequences are evidently leading astray, it is abandoned but if like Planck's, like de Broglie's, and like Bohr's—to go no further—they lead in a helpful direction, yielding results that can be compared with metrical determinations, then the hypothetical formula attracts attention and begins to be accepted as the basis of a partial theory, even though its full significance is not understood, the reasons for it only dimly apprehended, and though the agencies with their mode of working are in the main unknown

Experience has shown that a working hypothesis may be a true guide so far as it goes, even though it has in the end to be so extensively supplemented as to be revolutionised The precision attainable varies in different branches of knowledge only in a few subjects can the results be expressed and checked with numerical accuracy In physics and astronomy we have grown accustomed to these precise modes of verification, though even here the verification may not substantiate every detail of the original hypothesis or prevent its complete recasting in the light of further knowledge The quantum was appealed to as somehow securing the stability of Bohr's electronic orbits, but further treatment by Schrodinger put a different complexion on the electron and the final word has not yet been said Still, the quantitative results attained by Bohr's theory, spectroscopically verified to many places of decimals, were amply sufficient to justify us in enthusiastically welcoming the partial clue provided

Not often is such numerical precision attainable, sometimes only the order of magnitude can be checked, and sometimes the agreement with fact is not quantitative at all Even in chemistry the constitution of certain molecular compounds was arrived at by a special instinct, and was accepted long before physicists began to scrutinise the molecules and ascertain that their constitution was more or less in accord with the intuitions of genius In biology such direct verification is still far off, and seldom can any theories be brought to the test of quantitative determination In anthropology and sociology, in addition to all the other difficulties, an element of caprice enters in Humanity is not so amenable to law and order as molecules are, and individual behaviour can scarcely be predicted or specified with anything approaching completeness A statistical result may be arrived at, and the average behaviour of a large group can be stated with approximate correctness, subject to disturbing causes Even in molecular physics the laws of probability tend to supersede the accurate dynamics of individual occurrences, and we have to be satisfied with a sort of average uniformity variegated and enlivened by individual eccentricities

Psychologists and psychiatrists seek to penetrate the meaning of perverse peculiarities and to ascertain the laws of individual behaviour so far as they can The introduction of what we call chance and caprice makes a scientific treatment more difficult, undoubtedly, but it does not prevent the subject from being pursued in a scientific spirit Methods and results must vary according to subject matter and what would be vague in physics and chemistry may be unusually definite in subjects like biology and psychology Even in physics an element of indeterminism has recently been suspected certainly the molecules of a gas are behaving in an apparently lawless manner, while yet their average or aggregate behaviour on a large scale is satisfactorily uniform

As to the illegitimacy of hypothesis in science, that is absurd Every theory began as a hypothesis It is to test a hypothesis that every elaborately planned experiment is made As a digression it may be worth insisting that Newton himself constantly made hypotheses,—his queries at the end of 'Optics' are a collection of them,—and gravitational astronomy itself must have begun as a hypothesis When engaged in deductively working out results of theory on a mathematical scheme, he did indeed, and very properly, say, "I am not making hypotheses," using the present tense in a perfectly grammatical and intelligible manner though the sentence is often mistranslated or misinterpreted in a form covering both past and future, as if he had said, I do not make, or I never make, hypotheses Which would have been merely false

The ether of space is a hypothesis, rendered necessary by the complex behaviour and properties which have to be attributed to what we call empty space, that is, space empty of matter Regarded philosophically it seems impossible to imagine the space between atoms and worlds as really empty, it is only empty of everything that appeals to our senses and is amenable to direct experiment The nature of space is inferred, and has to be inferred, from its effects on matter but the inference that there must be something literally 'sub-stantial' in space, which is really responsible for cohesion, elasticity, and all the other manifestations, is inevitable, though in expressing such behaviour (electrical, optical, gravitational) it is the results and not the mechanism that we formulate, for the mechanism seems to be unlike any mechanism with which we are acquainted, and is still essentially unknown

Objections to the ether are really objections to the nineteenth century conception of an ether expressed

in terms of mechanical models No such ether exists the real ether is too fundamental an entity to be expressed in terms of the sensory perceptions of material behaviour, which is what we usually mean by explanation In so far as it is unexplained and not amenable to experiment—so long as it is a sort of hypothesis *in vacuo*—the ether may be disliked, just as Newton disliked the introduction of vague and ill understood causes, preferring to have none at all to account for action at a distance rather than some entity of which he neither knew nor could assert anything Electricity and magnetism were a sealed book then, and Clerk Maxwell was far in the future

There are, however, sciences of which the working hypotheses must be vague The mental sciences are peculiarly in that condition we cannot treat of mind in any quantitative manner The trivial details of experimental psychology skirt about the fringe of the subject, collecting data rather like those of old fashioned meteorology, in the hope that perhaps some day a comprehensive generalisation will arise which can reduce them to law and order

All this preliminary is for the purpose of (perhaps unnecessarily) insisting that science exists in many stages of development and that we are not at liberty to turn down a nascent science merely because it is still in an infantile and unmetrical or even a capricious condition Human activities cannot be denied merely because they are inaccessible to calculation and defy prediction

To take an extreme example What is called the spiritistic hypothesis is flagrantly objected to, for it appeals to the activities of unknown agencies which cannot at present be satisfactorily brought to book The supposed agents have human characteristics, and behave as if they were like ourselves, except that they are for the most part out of touch with matter, save under special conditions which it is our business to investigate if we can whereas we ourselves, when acting as agents, are not only conscious mental and spiritual entities, but are closely and continuously in touch with matter for a period of the order of a century Our action on matter makes our behaviour conspicuous and easy to observe, but it has not yet led to any explanation The connexion between mind and matter is still an unsolved problem, the mechanism of it is only very partially understood—the link between mind and brain is missing,—but that does not prevent our accepting the activities of, say, engineers and architects and artists as a fact They do deal with matter, in accordance with their plans and designs, whether we understand the process or not

So if hereafter we find ourselves still existing and active, after we have escaped from our normal organism,—if it turn out that under certain conditions we are able to use the organisms of others, so as still to affect material particles, especially the complex molecules of living protoplasm, and thus display surviving intelligence,—we should hope to be met, not by an *a priori* objection as to the possibility of such activity, but rather by a willingness to study the evidence and a determination to be guided by the facts, as in any other better established and more reputable branch of inquiry

Still, it does happen that even after some prolonged and impartial study of the facts, the hypothesis of what may be called posthumous activity is still disliked and still provisionally rejected as an attempt at explanation For example, my distinguished friend, Charles Richet, accepts all the phenomena that I do, or even more, but the tentative explanation of some of them as due to discarnate activity does not appeal to him or perhaps I should rather say is only very gradually beginning to appeal to him And there are other less well known members of the Society for Psychical Research who stand out against the spiritistic view and strive after every other sort of explanation,—thereby doing good service and constraining a supporter of the hypothesis to bring forward constantly better and better evidence and to realise more clearly the objections that have to be met

Again, I suspect that contributors to Nature, and the majority of its readers regard both the hypothesis and the phenomena which led to it with serious doubt and unconcealed dislike some indeed pour contempt on the whole thing as a savage superstition But the occurrence of the phenomena amid all races and in all periods though it may arouse prejudice is no valid argument against the reality of something responsible for those widespread superstitions Our business is to disentangle them from superstition and to dissect out whatever element of truth they may enshrine For it has been our experience that an element of truth often does underlie old legends Explorers often discover that old beliefs had a foundation after all witness Schliemann at Troy, Sir Arthur Evans at Crete and many other examples known to archæologists and palæographers An ancient belief can scarcely give any appreciable support to a scientific hypothesis but the existence of such belief is not really injurious and is by no means fatal to it On the whole, the existence of a tradition is rather favourable than otherwise At worst it is neutral

Objections to the Spiritualistic Hypothesis from a Scientific Point of View

With this preliminary let me comment on a sentence extracted from a paper which will shortly appear in the *Proceedings of the Society for Psychical Research*, in which an automatic writer who himself has produced script purporting to be inspired by a fairly recently deceased and comparatively unknown poet, expresses himself as sceptical about the ostensible and superficial significance of the scripts in the following words —

> " Regarded as a scientific working hypothesis, spiritism does not seem to me to be a very hopeful avenue of investigation The spirit hypothesis has a delusive appearance of simplicity, but so also had Kepler s hypothesis of guiding angels And how remote this was from the complex reality of Einstein's description of gravitation! In fact, if these supernormal mental phenomena depend on the whims and caprices of departed spirits, then I for one despair of ever being able to discover any law and order in them "

Undoubtedly there is some difficulty, in our present state of comparative ignorance, about specifying or formulating the spiritistic hypothesis in any precise and, so to speak, scientific manner, for it is an appeal to the activity of unknown agents acting by unknown methods, under conditions of which we have no experience, and by means of which we are unaware We get into touch, or appear to get into touch, with these agencies only when they have affected material objects, for example the brain, so as to produce results which appeal to our normal senses But the admission that we cannot understand how agents work does not justify our denial of the existence of such working As I have already hinted, a good deal of modern mathematical physics is in the same predicament We do not really understand how the properties of the ether, or of what it is now the fashion to call 'space time,' act in producing the material effect we call weight or gravitation We know a good deal about it, we can specify with precision the law of 'weight' in so far as it imitates the resultant of an independent and unscreened attraction of every particle for every other We can say that the earth acts nearly as if its whole mass were concentrated at its centre, that the law of force is different inside and outside, so that it changes abruptly when the surface is penetrated, and that the force attains a peak value at the surface, sloping down differently on the two sides We can speak of the state of strain or 'potential' to which the force is due, say that it is continuous across the boundary, give the law of its variation with distance, and so on

Newton, in fact, correctly formulated the whole theory of gravitation considered as action at a distance but the true mechanism of what seems like a condition of strain or warp in space, brought about by the very existence of matter, was beyond him, as it is still beyond us In philosophic mood, Newton was never satisfied with his mode of specification It merely gave the resulting effect of something that simulated the direct attraction of one body on another across apparently empty space, he had to leave the inner meaning of such mysterious action for future discovery

Einstein discarded the attraction or force exerted by a body at a distance, and replaced it by a geometry of space which would account for, or at least express, the resulting behaviour in a more intimate and, so to speak, less magical manner An inert body can only be perturbed or guided by something in immediate contact with it, even though the particular modification of that 'something,' which enables it so to act, may be due to the neighbourhood of a distant mass of matter, for reasons which remain to be explored

The fact that we sometimes have to postulate an unknown agency does not justify our attributing anything capricious to that agency We are ignorant of how the gravitational agent acts, but we know that it acts in accordance with law and order, so that the results can be duly predicted Einstein's view (if we may call it Einstein's, though in one form or another it must have been vaguely held by many) is after all *not* so very different from Kepler's asserted hypothesis What Kepler meant by "guiding angels controlling the planets" (assuming that he used that phrase) I do not know, but I am sure he meant nothing capricious He must have meant that an unknown something guided the planets in their path, and that is a paraphrase of the modern view The 'something' is now often spoken of as a warp in space In so far as Kepler postulated something in immediate touch with a planet and acting directly on it, he had what now appears to be truth on his side, his thesis being perhaps nearer the ultimate truth, though far less practically useful, than Newton's delightfully simple quantitative expression for the indirect action of a distant body

In order to illustrate direct guidance by contact action, we might take the familiar example of a gramophone needle, which automatically reproduces a prearranged tune, simply by following the path of least resistance What else, after all, can an inert thing do? That is the meaning of inertia Animated things are not inert, they need not take the easiest path A man may climb the Matterhorn for fun But inanimate unstimulated matter never behaves with any initiative or spontaneity, it is strictly inert Atoms never err or make mistakes, they are absolutely law abiding If they make an apparent error, if a locomotive engine leaves its track, we call it a catastrophe All machinery works on that principle every portion takes the easiest path It is true that to get a coherent result there must have been planning and prearrangement Certainly! In all cases of automatic working, whether biological or other, that must be an inevitable preliminary But explorers of the mechanism will detect no signs of mental action by their instruments or their senses To infer a determining or controlling cause they must philosophise Indeed, we may go a step further, and emerge from the past into the present, thus A wireless set talks like a gramophone, and to one accustomed only to gramophones it would seem barbarously superstitious to urge that in the wireless case some (possibly whimsical and capricious) operator was actually in control Statements may be unpalatable, and yet be true

Now return to gravitation Planets behave as if they were attracted by the sun That is certainly true But what is attraction? A train is not attracted to its destination lightning is not attracted to a chimney, but it gets there none the less, by continually taking the easiest path So it is with a planet Indeed, one might say that everything inert takes the only path open to it, it has no option The law is a sort of truism But the principle, once recognised, has been formulated into a clue the Principle of Least Action can be expressed mathematically Once postulate that, and the behaviour of the inanimate portions of the cosmos can be accurately deduced

The modern statement that the planets move along the line of least resistance, or the easiest path, makes their motion rather closely analogous to that of a railway train guided by the rails The path and destination of a train are determined by the

continual direct influence of the rails, which make it easier for the train to travel in the right direction than to jump them and go astray We might, if we chose, admit that the path was laid down or determined by the mentality of the surveyors and designers of the route, but a Martian spectator with partial information might still wonder at the apparent intelligence which guided one part of a train to Manchester, and another part to Liverpool, in accordance with the wishes of the passengers or the labels on the coaches If told that an invisible guardian angel switched over the points to produce this result, he might resent the suggestion as absurdly unscientific and preposterous, as on a purely mechanistic view it would be

After having studied trains for some time, our spectator might begin to notice the novelty of a motor car His first tendency would be to look for the rails in that case also, and, finding none, he might superstitiously but correctly surmise that a guardian spirit was guiding the car to its destination In this case, moreover, further experience would soon persuade him that he had to allow for an element of caprice But even that is not fatal to the truth he need not throw up his hands in despair As soon as we introduce the activity of life and mind we get out of mere mechanism, and the results are not easily formulated or predicted The activities of an animal cannot be expressed in mathematical terms, and yet animal instincts and behaviour are subject matter for scientific investigation It is assumed that they obey laws of some kind

Science is not limited to the accurate data and laws of mathematical physics and to claim that a hypothesis is unscientific because we cannot formulate it completely, or because we do not understood the method of working, or even because there is a certain amount of capriciousness about it, is more than we have any right to claim Anthropology and sociology are less advanced sciences than physics and chemistry, they have to get on as best they can, with a profusion of data, and with the inevitable complications appropriate to live things Let us not be put out of our stride by the fear of retaining, in modified form, some of the animistic guesses of primitive man Experience may lead us, as it led him, to contemplate stranger modes of existence, and more whimsical phenomena, than our long study of mechanism has led us to expect We must put aside prejudice, be guided by the evidence, and strive for truth The superficial simplicity of materialism has served us well, as a comprehensive covering, for three centuries, and we have made good progress under its protection, but it is beginning to be threadbare and inadequate, it is not co extensive with reality, and unsuspected influences are peeping through

To sum up A working hypothesis can be followed and developed rationally, without being metrically exact in its early stages The important question about the spiritistic hypothesis is not whether it is simple or complicated, easy or puzzling, attractive or repellent, but whether it is true Its truth can be sustained or demolished only by the continued careful critical and cautious method of inquiry initiated by the S P R under the presidency of a guiding spirit or guardian angel called Henry Sidgwick, with the active (and I believe continuing) co operation of Edmund Gurney and Frederic Myers

The Supply and Therapeutic Uses of Radium

By Prof S Russ, The Middlesex Hospital

THE law of supply and demand is as true for radium as other commodities Production has often almost ceased owing to lack of demand, only to be renewed as the demand returns, while sudden demands have sent up the price to prohibitive levels until either competition or diminished requirement has brought it down again

The three main sources from which radium has been mined on any scale are Czechoslovakia, the United States of America, and the Belgian Congo, Cornwall and Portugal have also been producers, though on a smaller scale The low grade of the carnotite deposits in U S A made it impossible for America to compete with production from the large deposits of pitch blende located by the Union Minière du Katanga in its property in the Congo since this rich source has been developed Czechoslovakia still produces radium, and in Great Britain there is very little difference in the price of radium coming from there or from the Belgian Congo Unless the amount bought is as much as several grams, the price is at present £12 per milligram of radium element, with extra charges for certificates of measurement and other services connected with the supply This price is doubtless one which yields a very big profit to the producers, and it is worth while mentioning that the price of the Belgian radium is graded according to the national purse of the buyer—Britain pays more than do her continental neighbours, and America pays more than Britain There is radium enough in the earth for the world's needs if it can be paid for
